Ham items at a garage sale are a RARE item,
and either the ham that found these at a garage
sale was VERYLUCKY (at the right time),
or a ham that went to a LOT/regularily,
or was both!

Butch,

$200.00. It appears that this rig sat in a garage(unheated) of an SK for about 5 years. All the control worked smooth and weren't noisy. The front panel was in VG shape, and the VFO was smooth. Plenty of HV. There were lots of "radio things." It appears that this may have also had or an aborted CB hack. I found some wiring changes that appear to have been reversed between the counter unit and the PLL board.....the solder job was very poor and what was taped up was poor also. So, going to have to go through this unit and double check. It does work on all bands...just that 160m is off. Also, found a damaged L4 on the RF board that's going to have to be replaced....guess I'll have a project for a bit.....

Joe,

Ignore the step 18 that addresses the "AM" portion. This applies to TS-830M models only. Step 18 on page 37 titled "Generator Drive Coil Adjustment" is the step I am referring to.

Hi Joe,

Bob Mansker, ke5ftf at mail.com most likely has a replacement RF Unit board. You might check with him to see what he can do for you. I recently purchases a replacement RF Unit board for my 820. It worked great and his prices are reasonable.

Hi Mike

Thanks for the expert advice on the ALC adjustment. I will resurrect my AG, and get the scope and counter on it to do it right.

But, the original problem still exists: low output on 17m. I can get 5-7 watts out in CW mode, CAR pot fully CCW. Drive peaks output, plate adjustment dips IP, load peaks up RF, the works, but not more than 5w.

I have confirmed continuity on S1-7 wafer, removing the coil and measuring resistance from the contact (making sure it went through the rivet) to the point under the RF board where it enters the coil for 17m. No resistance there. I have done the VCO check, I have measured the RF VOLTAGE at TP4 on the RF board, I have measured the DRV level with the RF vm (HP3400A). ALL appears normal, but it just won't tune 17m.

I have swapped tubes (both driver and finals), I have inspected and confirmed low resistances on S1-7. Even though in tune mode, it's not in play, I have checked the switch contacts in the final compartment. All seem fine. All voltages right where they should be on both driver and finals.

It just won't tune up on 17m?

Any parting comments on what to check?

73 Kevin K7ZS

Hello Kenwood owners !!

Trying to figure out a odd change in my ts-830s , rig has been rack solid foe a year... here is what happened . In the past while tunning up in cw mode with my load knob all the way off < minimum> my IP scale would be around 150 mA with about 60 watts output... then I would turn my load knob up until 100 watts output and the ip would read 220mA. Now for some reason with load knob at minimum the current is 240MA with 70 watts out and I have to jack up the current to 260mA to get 100watts. I cant get the current below 240mA when in the past I could go as low as I wanted.

Yes this is after dipping the plate ..etc .. I repalced the finals and driver tube with known good ones...same results !! any takers? I suspect something in the rectifier board .

John,

Check the value of the 4 20 ohm resistors on the final board...they should be no more than about 5.6 ohms to ground. Also, check the 100 ohm resistors on the final board too...and the 470 ohm resistor on the rectifier board. You do not have to dismantle the final board...get an X-RAY view schematic out of the service manual..check n6wk web site....good luck.....

WHY ?
Is something wrong with the analog dial?
I have had the original TS520(no S) for over 35 years and the circular analog dial is great if you calibrate it properly..
Never had any desire to add any digital readout to it.

From: "pmarkavage@..." <pmarkavage@...>
To: TS-520_820_530_830@yahoogroups.
No easy way to use a "regular" frequency counter, without some addtional circuitry, to view actual frequency of the TS-520SE. You're better off finding a Kenwood DG-5 or Spectronics DD-1K digital displays that were designed to work with rigs like the TS-520 series.

John, I think that this obsession (if I may call it that) over digital readouts is a symptom of a trend that I am noticing on the ham bands. If a station is off an even frequency by something like 1.3 Khz, someone is likely to come along and tell the operator that he is "off frequency", even though his signal might be WELL WITHIN his allocated range for his license.

There is only one band in which exact center frequencies are a requirment, and that band is NOT supported by the 520. It seems rather silly to me that operation on something other than an even frequency (14.230.00.00 as opposed to 14.231.24.5) is reason to be called out by someone else, but it seems to be happening more and more often.

One of my radios is PLL controlled, but the closest to a given frequency I can get is 10Hz, and I usually don't use that, but rather, tune in 100Hz increments. The other one is a pair of 599 twins, and I would NEVER want to put a digital dial on them! That would be like hanging a foxtail on the rearview mirror of a Ferrari !

73, Jim AG3Y

Oh, there's nothing wrong with using the dial readout, I just thought it'd be nice to have a digital readout. Like I mentioned before, I got the frequency meter mainly for testing and diagnostic purposes. It just would have been an added bonus if I could have hooked it up to me 520SE as well.

You could add a RF sensor (germanium diode and some wire) to the input of the counter, and depending on how much RF is floating around your shack when you're transmitting and how sensitive the counter is, the counter will detect and read the frequency your transmitting on. Not extremely elegant, but you can dazzle your contacts with decimal accuracy. It can also indicate if your VFO on transmit is drifting around.

I think it is more of a SSB thing where you have to be really netted with the other operator(s) on freq to sound right. You would not like to sound like a chipmunk or Klingon warrior.
You would not bother the other end ot the qso to have to dig thru menus to find how to enable and use the RIT function !
CW is more forgiving if you are 500 Hz off the other op's freq.

Subject: Re: [TS-520_820_530_830] TS520SE and Heathkit frequency meter

John, I think that this obsession (if I may call it that) over digital readouts is a symptom of a trend that I am noticing on the ham bands. If a station is off an even frequency by something like 1.3 Khz, someone is likely to come along and tell the operator that he is "off frequency", even though his signal might be WELL WITHIN his allocated range for his license.

There is only one band in which exact center frequencies are a requirment, and that band is NOT supported by the 520. It seems rather silly to me that operation on something other than an even frequency (14.230.00.00 as opposed to 14.231.24.5) is reason to be called out by someone else, but it seems to be happening more and more often.

One of my radios is PLL controlled, but the closest to a given frequency I can get is 10Hz, and I usually don't use that, but rather, tune in 100Hz increments. The other one is a pair of 599 twins, and I would NEVER want to put a digital dial on them! That would be like hanging a foxtail on the rearview mirror of a Ferrari !

No easy way to use a "regular" frequency counter, without some addtional circuitry, to view actual frequency of the TS-520SE. You're better off finding a Kenwood DG-5 or Spectronics DD-1K digital displays that were designed to work with rigs like the TS-520 series.

Well, 500 hz away from another operator when working CW is still a pretty good hop, unless you are purposefully running "split". However, I have heard stations running up to 500 hz apart, and neither operator seems to be aware that he is that far away from the other station! Amazing!

A frequency counter, picking up RF off the air, can be more accurate, at least for the transmitted signal, provided that it is calibrated against a good standard. WWV is plenty good enough for amateur radio use. The signal from the time-base oscillator is zero beat against one of the WWV station's carriers, and the result should provide a good base for all your measurements.

Of course, Mike knows this. I am just mentioning the procedure for those who are just getting started in this avocation!

I agree with Jim.

The DG-5 has an internal 10Mhz standard oscillator. The calibration adjustments are covered on page 36 in the DG-5 service manual.

The nice thing about the DG-5 is it can be be used as a simple frequency counter as well as displaying receive and transmit frequency when connected to the TS-520S and TS-520SE. Mods to bring the HET, VFO, and CAR oscillator signals to the rear panel of the TS-520 is required in order to use the DG-5 with the TS-520.

Mike & group,

Found a good L4 on a bad RF board in the parts bin and replaced the broken one. While I was in there, took out the IF board too and cleaning it and the RF board in DAWN dish soap really did the trick. All back together now and turned on. Two questions though: what the heck is an AF VTVM,? and is it necessary to have it to do step #20 in the service manual? I have an o'scope, vtvm, and dvm w/rf probe. tnx.....

From: Will
Topic: 29977 Message: 29977

Hi everyone; I know this sounds like a rather academic type question but could/would someone explain to me about neutralisation of paired tubes in the 830 and its requirement(s). Having taken delivery of a beautiful example of the 830s, I need to try and understand this particular requirement should new valves be required at some point. Can you explain (a) what it is and detail specifically how to do it (b) why it is necessary (c) the easiest way to perform this without an rf probe/VTVM, ie, is the second receiver technique effective/anyway good and (d) implication of not doing it. Although kicking around this great hobby for nearly 25 years, I have been in semiconductor land for most of that time and valves is a whole new game to me. Thanks in anticipation.....Will / GM0HKS

Hi Mike...
...and Everybody,

I have noticed widespread misunderstanding on the lists and on the air about the difference between dial resolution and dial accuracy. Obviously some of the members here have a good idea about that. Once upon a time I was considering how to hook up a digital display to a Hammarlund receiver. Before I could get one built I learned how to use the dial that was already on the receiver. There was no real need for the digital dial.

Digital dials might be more convenient than counting off those funny little marks on the dial, especially if your eyesight is fading a little. We just have to keep in mind that 10 Hz or 1 Hz or .001 Hz resolution on the display is no guarantee that's your exact, absolute frequency. This doesn't even address the whole idea of transferring a standard and the concept of tolerances.

If you have access to the 1976 ARRL Handbook (and perhaps others) there is a digital frequency readout as part of a receiver project that would be suitable for any of these radios. If you just want to know more you can look there and not bother about building it. The receiver project starts on page 274. That's the one I was going to build for the Hammarlund. It was faster and easier to learn how to use the calibrator and interpolation than to build that dial <evil grin>. I was able to dial up a MARS traffic net by the dials alone and have the rig right on the net.

The dials on my 599 Twins are more than adequate for ham use. I do have a digital frequency counter on my bench sharing space with a WWII LM <g>.

73,

Bill KU8H

From: Jim S
Topic: 29947 Message: 29979

With all the digital dials, etc. that have pervaded the market, a simple little device has essentially been lost to the ham radio avocation! I am talking about the 100Khz crystal calibrator. The simplest ones gave "marks" every 100Khz up the HF band. More advanced ones would have a divider circuit that would split that 100Khz frequency into 25Khz increments.

Many of the older radios such as the Kenwood hybrids had crystal calibrators either built in or available as an "option" at a small charge. I can still remember the Heathkit calibrator that plugged into an octal socket on the chassis.

When these devices are set up right, it is extremely easy to see exactly where the edges of the bands, and/or your allocation falls on an analog dial. The calibration marks on those dials were either lined up by holding the knob skirt and turning the innner knob to adjust the VFO without moving the dial itself, or perhaps by turning a small knob on the front of the radio that would adjust a small trimmer in parallel with the VFO capacitor and move the frequency far enough to allow the dial marks to be in the right spot.

Unless something was seriously wrong with the radio, most dials would agree within a few Khz of the marker, and a simple twist of the right knob was all it took to get very close to the right frequency.

Did they give you fractions of a Hz resolution ? NO ! Were they "close enough for Government work" ? Well, YES, as long as you used common sense and didn't try to put your suppressed carrier ON the band edge, and hope that all your sideband energy was within the band, or didn't try to put your CW carrier on the other band edge, and hope that it was "close enough". Even the seasoned Extra Class operators knew enough to stay a couple of hundred Hz inside the band, just to "make sure" !

Sadly, that skill, and those tools seem to be disappearing with the newer operators and radios.

I really wonder how many "appliance operators" know how to check the calibration of their digital dials ?

Hi Mike...
...and Everybody,

I have noticed widespread misunderstanding on the lists and on the air about the difference between dial resolution and dial accuracy. Obviously some of the members here have a good idea about that. Once upon a time I was considering how to hook up a digital display to a Hammarlund receiver. Before I could get one built I learned how to use the dial that was already on the receiver. There was no real need for the digital dial.

Digital dials might be more convenient than counting off those funny little marks on the dial, especially if your eyesight is fading a little. We just have to keep in mind that 10 Hz or 1 Hz or .001 Hz resolution on the display is no guarantee that's your exact, absolute frequency. This doesn't even address the whole idea of transferring a standard and the concept of tolerances.

If you have access to the 1976 ARRL Handbook (and perhaps others) there is a digital frequency readout as part of a receiver project that would be suitable for any of these radios. If you just want to know more you can look there and not bother about building it. The receiver project starts on page 274. That's the one I was going to build for the Hammarlund. It was faster and easier to learn how to use the calibrator and interpolation than to build that dial <evil grin>. I was able to dial up a MARS traffic net by the dials alone and have the rig right on the net.

The dials on my 599 Twins are more than adequate for ham use. I do have a digital frequency counter on my bench sharing space with a WWII LM <g>.

73,

Bill KU8H

Joe,

A AF VTVM is a voltmeter with a calibrated scale in db, with an input impedance of 600 ohms. You can substitute this by using your own VTVM and put a 600 ohms resistor over the input, that will do the trick too. Almost every VTVM meter has a seldom used db scale.

hope this helps,

Hi All,

I built my own VTVM based on an Australian hams design, that works VERY well, and I couldn't do without it now... This one has a analogue meter, 5 ranges up to 500mV, 1V, 5V, 10V and 20V.

If anyone wants the design details and component list, please let me know.

Thanks
Chris, ZL1CDP

Can you explain (a) what it is and detail specifically how to do it

Neutralisation is preventing the tubes to go in self-oscillation by blending out the internal tube capacitance, the usual source for VHF self-oscillation.

b) why it is necessary

If not done the tubes can (and will) produce a signal in the VHF range and causes trouble in TV, Airband or other frequencies.

(c) the easiest way to perform this without an rf probe/VTVM, ie, is the second receiver technique effective/anyway good and

The easiest way to do it is the "cold method"
You run the TX on 10 meters and tune for maximum output into a dummyload.
Then you switch off the heaters of the final tubes by removing the accessory socket. The driver tube stays on.
Put a T-piece connector between the set and dummy, for connecting a meter, a SWR meter will not do. Let the dummy connected.
Connect a scope or RF millivoltmeter to this connector and set for a comfortable readable signal strenght.
You may also use a second receiver's S-meter instead of the scope, but the receiver must be connected directly, otherwise you pick up all kinds of stray signals.

Then set the TX in transmit after you have checked double that the heaters of the PA are disconnected.

Tune the neutrodyne condenser for minimum signal.
Be very careful: usually one end of this capacitor is on 900V and that is no voltage to ignore.
Use a good isolated adjustment tool, not a normal screwdriver, because that induces more capacity to the circuit.

Remove the measurement instrument, reconnect the accessory socket, you set is neutrodyned.

That is all, you just compensated the internal tube capacitances and there should be no "wild" oscillations.

There are more elaborated ways to do this, but I always used this method that was used on VHF when the transmitters had still tubes.

d) implication of not doing it.

Hi again WimI have read your instruction details again and have a couple of more questions. I hope you will understand as I am not totally familiar with the 830 and valve principles:

Then you switch off the heaters of the final tubes by removing the accessory socketWhat does this mean exactly. Do I have to physically remove the socket ? desolder the wiring to it or what ?
also
Then set the TX in transmit after you have checked double that the heaters of the PA are disconnected.I was assuming that by switching the heaters off for the final tubes on the front panel control this is what you refer to. Perhaps you would advise.

neutrodyne condenser _ by this do you mean TC1 underneath the final printed circuit board ?

29989. PLATE CURRENT VERSUS OUTPUT POWER

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-02-27 15:08:51 UTC
From: Will
Topic: 29989 Message: 29989

Is there a reasonable mean average/relationship between plate current and power output with regard to the TS830s. I should be able to calculate I2R, P=VxI etc but what I think I am trying to say is that I would like to establish if my rig is operating within safe parameters for example, on 40 metres with an output power of 60 watts my IP reading is 210ma and at 100 watts it readings 270ma. Is this around the norm or does the plate current seem a little high ?

regards

Will

Topic: 29977 Message: 29990

Hi Will,

Just a few added bits of information to Wim's resposne.

Tube amplifiers have what is called unwanted internal capacitance between that exists between the output and input elements. The unwanted capacitance between the output element and the input element within the tube(s) can cause the output to couple back to the input causing "regenerative feedback" to occur. Regenerative feedback can result in loss of amplifier efficiency, maximum RF output will not occur at the maximum plate current dip, and/or cause the amplifier to "oscillate".

The neutralizing capacitor, typically a variable capacitor and is listed on the hybrid schematics as "TC1", connects the amplifier's output to the amplifier's input at 180 degrees out of phase. The neutralizing capacitor, when properly adjusted, cancels the unwanted tube element capacitance, eliminating regenerative feedback

Neutralization does not "drift" out alignment due to age of the tube(s) since the tube's internal capacitance is set by the design of the tube and is not affected by age.

The hybrid service and operator manuals list the steps required when neutralizing the final amplifier in the hybrids.

Hi All, I will post it to the files section.

Note, it's not an old style Vacum Tube Voltmeter, but a more modern RF Voltmeter design.

Hope it helps you all.

Cheers
Chris, ZL1CDP

29992. RF Voltmeter design files

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-02-27 17:36:23 UTC
From: Chris Parnell
Topic: 29992 Message: 29992

Hi all,

I couldn't post this to the group as it's 2MB in a zip file, so I have hosted it on my www.ft-2000.com website.
You can download the file here:

http://www.ft-2000.com/RFVTM.zip

If you want to download the file from a web browser, please ensure that the RFVTM portion of the url is in UPPERCASE, as it's hosted on a unix server and therefore case-sensitive.

As mentioned in a previous email to the group, this is not an older Vacum Tube variety, but a very accurate, modern, RF VTM that is easy to build and use which helps tremendously with aligning your HF hybrid rigs. - Great for neutralization and general alignment.

Lastly, just to mention that this is not my design, it is from a VK ham.

Thanks
Chris Parnell, ZL1CDP

Hi Will,

Just a few added bits of information to Wim's resposne.

Tube amplifiers have what is called unwanted internal capacitance between that exists between the output and input elements. The unwanted capacitance between the output element and the input element within the tube(s) can cause the output to couple back to the input causing "regenerative feedback" to occur. Regenerative feedback can result in loss of amplifier efficiency, maximum RF output will not occur at the maximum plate current dip, and/or cause the amplifier to "oscillate".

The neutralizing capacitor, typically a variable capacitor and is listed on the hybrid schematics as "TC1", connects the amplifier's output to the amplifier's input at 180 degrees out of phase. The neutralizing capacitor, when properly adjusted, cancels the unwanted tube element capacitance, eliminating regenerative feedback

Neutralization does not "drift" out alignment due to age of the tube(s) since the tube's internal capacitance is set by the design of the tube and is not affected by age.

The hybrid service and operator manuals list the steps required when neutralizing the final amplifier in the hybrids.

Hello Will,

I am also not very familiar with the 830, more used to the FT101ZD and FT901DM. They have a accessoire socket for a external 2M transverter, that can be used to interrupt the 12 to the finals.

My mistake: looking in the schematic shows that the 530 has not such convenient plug, so you have to break the 12V to the heater elsewere.
Switching off the heater voltage on the front kills also the 12BY7 heater and that is not wanted in this case.
So desoldering the 12V connection to the final board is the quickest solution.

Yes, TC1 is the neutrodyne condenser.

Generally you can use this neutrodyning method on every tube-type transmitter, if you switch off the heater to the final and tune the neutrodyning condenser for minimal output of the PA stage.

73, Wim PA0PGA

Topic: 29989 Message: 29996

My TS-820S runs 100W out with an Ip of 200mA on 40M. 225mA will give me 125W out but I don't push the tubes that hard.

73,
Alan, KD5R

Subject: [TS-520_820_530_830] PLATE CURRENT VERSUS OUTPUT POWER

Is there a reasonable mean average/relationship between plate current and power output with regard to the TS830s. I should be able to calculate I2R, P=VxI etc but what I think I am trying to say is that I would like to establish if my rig is operating within safe parameters for example, on 40 metres with an output power of 60 watts my IP reading is 210ma and at 100 watts it readings 270ma. Is this around the norm or does the plate current seem a little high ?

regards

Will

From: w5rkl
Topic: 29977 Message: 29997

Actually, Wim, you need the driver tube's RF signal when adjusting TC1 to neutralize the final amplifier. What needs to be done is the final tubes must be stopped from producing RF output and that is accomplished by setting the rear panel SG switch to OFF. With the SG switch set to OFF, a "negative" voltage is applied to the screens of the final tubes. This prevents electron flow from the cathode to the plate, turning both final tube cathode to plate conduction "OFF".

Other transceivers, when neutralizing the final amplifier, states to remove both plate and screen voltage, this is how Heathkit neutralizes the final amplifier in the HW-100 and SB-100 series transceivers, excluding the HW/SB-104.

Regardless of the transceiver, the driver tube must function as normal.

As for operating the Kenwood hybrids, 520 and 820, with the Kenwood Xverter, the driver tube is not turned off, it remains operating as it normal does. The final amplifier is turned off by setting the SG switch to OFF. The filament switch remains "ON" at all times. The "Xverter" requires a driver tube 10 meter signal in transmit and if the driver tube is turned OFF (Heater switch set to OFF) then there will be no RF signal being applied to the Xverter in transmit resulting in no RF output to the Xverter to mix with the Xverter's transmit local oscillator which results in no RF output from the Xverter.

Topic: 29989 Message: 29999

Thanks Alan, yep, I think the IP on this rig is running a little high and that is why I am trying to ascertain from as many individual 830 owners as is possible, if their plate current versus output power differs greatly from mine. Once I get some figures from others, I can then set about working out what is going on with this rig
regards

Will

Subject: [TS-520_820_530_830] PLATE CURRENT VERSUS OUTPUT POWER

Is there a reasonable mean average/relationship between plate current and power output with regard to the TS830s. I should be able to calculate I2R, P=VxI etc but what I think I am trying to say is that I would like to establish if my rig is operating within safe parameters for example, on 40 metres with an output power of 60 watts my IP reading is 210ma and at 100 watts it readings 270ma. Is this around the norm or does the plate current seem a little high ?

regards

Will

30000. Voltages are now correct after installation of new AF AVR board

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-02-27 20:59:01 UTC
From: ae5uu
Topic: 30000 Message: 30000

Good afternoon Mike,

I received the board last evening, have installed it, and found the following which I believe to be correct:

AF AVR AF1 pin 1 9.06vdc
pin 2 9.06vdc
AF AVR AF2 pin 6 3.37vdc

IF Unit pin 5 9.06vdc
pin 4 14.4vdc

PLL Unit PLL2 pin 3 (labeled 9) 8.78vdc

FIX-VOX Unit FX3 pin 1 9.06vdc

Relay Unit RL1 pin 1 no pin 1
pin 2 9.06vdc
pin 3 9.06vdc
pin 4 ?
pin 5 15.44vdc
pin 6 Ground
pin 7 14.37vdc
pin 8 14.37vdc
pin 9 14.37vdc
pin 10 14.37vdc
pin 11 14.4vdc
pin 12 14.4vdc
pin 13 4.85vdc
pin 14 Ground

RL2 pin 10 9.06vdc

RF Unit RF2 pin 1 9.06vdc

FUNCTION Switch to FIX-R FIX LED is on
FUNCTION Switch to VFO VFO LED is on
RIT Switch to On RIT LED is on
RF ATT Switch to On ATT LED is on

Now my problems seem to have shifted downstream:

With power on, and heater on, in receive, I show a reading on the meter of 220ma or 650 volts or etc. (I do not know what is being measured here) in all positions of the meter switch. In all cases, the meter reads e.g. 250ma at first and reduces to 220ma over 4 or 5 seconds, or 725 volts quickly down to 650 volts in the same period. I hear what sounds like a relay (maybe it always made that noise?), but it is not the transmit relay.

1) I have 900vdc in the HV section, meter on HV, in transmit (as I mentioned, 650 volts or 220ma or whatever on receive.)
2) Mode set at SSB, when I transmit, meter set to IP, I have no plate current of 60ma. In receive I have the same crazy meter reading.
3) Mode set to TUN, meter to ALC, in transmit, I CAN MAXIMISE meter reading with the Drive control. The reading is 10% higher than I am used to seeing in the past. In receive, the same crazy meter reading.
4) Meter set to IP, Mode set to TUN, no current for the Plate control to dip. On receive, same crazy meter reading.
5) Meter switch set to IP, Mode set to CW, in transmit no reading. NO crazy meter reading in receive. Change in Load control has no effect. Here I AM looking for 225ma but have nothing.
6) Meter switch to RF, adjust Plate and Load controls. No reading to adjust in transmit. Same crazy meter reading in receive.
7) Meter back in ALC, there is some microphone response but the level is only apparent above the initial crazy reading on the meter (meter does not zero.)

Thank you again for the board. What are your thoughts on my new problems? Thanks

73,

Russell

30001. Re: PLATE CURRENT VERSUS OUTPUT POWER

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-02-27 21:08:20 UTC
From: w5rkl
Topic: 29989 Message: 30001

The "IP" meter indication is a combination of final tube screen and plate current. The ICAS (Intermittent Commercial Amateur Service) maximum screen current rating of a single 6146 is "12.6ma", 2 times that for 2 tubes in parallel, and the max 6146 screen voltage is 250VDC. Therefore, to determine the actual final tube plate current, subtract approximately 25ma from the IP meter reading, that will be the approximate final tube plate current.

If one runs higher power output which results in higher IP current, current levels that exceed the 6146 maximum screen current rating, damage to the final tube screens can occur.

Amplifier power input is determine by the formula

Pin = IP x HV

Where "Pin" is "Power Input", "IP" is the combination of final tube screen and plate currents, and "HV" is the High voltage to the plates of the final tubes at normal FULL output!

Therefore, if the IP meter indicates 225ma and the HV indicates 875VDC the power "input" in the final amplifier would be approximately:

.225 x 875 = 196.875 watts

The power output numbers above are a combination of both final tube screen and plate power, minus any loss of RF output due to grid current flowing (ALC indicated) in the final tube grids. When grid current flows in the final tubes power is consumed in the grids resulting in a loss, reduction, of power output from the final tubes to the PI Network.

The final amplifier's in the hybrids operate in Class AB1 which has a typical efficiency ratio of 55%, power input verses power output. Therefore, with 196.875 watts input, with 55% efficiency ratio of power in verse power out, the approximate power output would be 108.2 watts out at the rear SO-239 (196.875 - 45% = 108.2 watt).

The power input figures shown above is/are the "DC" input NOT the "PEP" input power level. The power output figures are based on typical power loss percentages in a typical Class AB1 RF amplifier.

PEP output cannot be measured by monitoring the IP and HV readings as they change too rapidly during normal sideband operation. A calibrated PEP watt meter is the only way to determine the approximate PEP RF output of the transceiver in sideband. The PEP watt meter output accuracy, or any watt meter accuracy for that matter, is also governed by the manufactures percentage of error.

Hi Russell,

The HV sagging to 650VDC appears to be a HV filter capacitor failure, one of the HV filter caps has failed. I recommend replacing "both" HV filter capacitors along with both 470K 1/2 watt resistors and both .001ufd 2KV disc capacitors. See Ken, K4EAA, website

www.k4eaa.com

for HV replacement filter capacitor kit.

Do that then we can look at any other problems your 820 may have.

Mike,

As per 1) below, I have a nice solid 900 volts out of the HV capacitors. Earlier today I changed them, the two small capacitors and the two resistors out anyway. I still have a solid 900 volts. It is the confusing meter readings when the set sits there in receive that I don't understand. As I mentioned, I don't know what the meter is measuring, but it is the same in all meter switch positions. If the HV reading on the meter is supposed to read 900 volts on receive and transmit, then I do not have that; just transmit. Could my driver tube be causing any of this trouble?

73,

Russell

Alan,once again, I am extremely grateful for the math calculations. I'll take time out tomorrow to evaluate the rig HV reading, plate current and try the calculations in order to ascertain what the 830 is radiating. This has been a great exercise for me and, I suspect, others too. Very many thanks once againWill

30009. RE: [TS-520_820_530_830] PLATE CURRENT VERSUS OUTPUT POWER

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-02-28 00:13:37 UTC
From: Robert Herendeen
Topic: 29989 Message: 30009

I get 90 watts at 200ma and 105 watts at 230ma on 40mtrs.

More plate current does not get me more power out, so 230ma is about max on 40 for this 830.

Bob/W6JZR

Subject: Re: [TS-520_820_530_830] PLATE CURRENT VERSUS OUTPUT POWER

Thanks Alan, yep, I think the IP on this rig is running a little high and that is why I am trying to ascertain from as many individual 830 owners as is possible, if their plate current versus output power differs greatly from mine. Once I get some figures from others, I can then set about working out what is going on with this rig
regards

Will,

Are you sure that the "meter" is accurate? Measure the the 4 20 ohm resistors on the final board. You do not have to remove the board to test. They should be no more than 6 ohms to ground(20% tolerance), the closer to 5 ohms to ground the better. The higher the ohms, the more the Ip reads and the lower the power. If I remember right, these affect plate current metering. Find an X-RAY view of the final board to locate the resistors in question. Check out n6wk.com and the high-rez service manual. My 830S & 820S will usually put out a full 100 watts on all bands (except 10 meters) with 220 - 240 mA of Ip. Also, don't trust the meter on the front to be accurate reading the HV. Measure at the HV caps or the "800" terminal on the rectifier board. I have seen meters be of by as much as 90v due to out of value resistors in the metering circuit. Good luck.....

Subject: [TS-520_820_530_830] PLATE CURRENT VERSUS OUTPUT POWER

Is there a reasonable mean average/relationship between plate current and power output with regard to the TS830s. I should be able to calculate I2R, P=VxI etc but what I think I am trying to say is that I would like to establish if my rig is operating within safe parameters for example, on 40 metres with an output power of 60 watts my IP reading is 210ma and at 100 watts it readings 270ma. Is this around the norm or does the plate current seem a little high ?

regards

Will

Hello all, I need to know the detailed tuning sequence for ssb operation using an Ameritron 811 with an 820s. The instructions aren't very clear about when to key with the cw send switch or when to use the ptt switch on the mike for tuning adjustments. One more question; is there any nets for Kenwood hybrid owners ? Thanks in advance to an awesome group.

As usual, you are right Mike,
I have read the directions in the 830 manual, and the SG switch is even a more convenient way than disconnecting the 12V.
I was just not sure if there was still some output with full drive from the driver, because the 6146B acts as a (bad) triode when only the screen grid is off.
One way or the other the 12BY7 driver must be on as I already stated.

All in all the directions in the manual are in fact the same as I mentioned and should work fine.

>
> Actually, Wim, you need the driver tube's RF signal when adjusting TC1 to neutralize the final amplifier. What needs to be done is the final tubes must be stopped from producing RF output and that is accomplished by setting the rear panel SG switch to OFF. With the SG switch set to OFF, a "negative" voltage is applied to the screens of the final tubes. This prevents electron flow from the cathode to the plate, turning both final tube cathode to plate conduction "OFF".
>
> Other transceivers, when neutralizing the final amplifier, states to remove both plate and screen voltage, this is how Heathkit neutralizes the final amplifier in the HW-100 and SB-100 series transceivers, excluding the HW/SB-104.
>
> Regardless of the transceiver, the driver tube must function as normal.
>
> As for operating the Kenwood hybrids, 520 and 820, with the Kenwood Xverter, the driver tube is not turned off, it remains operating as it normal does. The final amplifier is turned off by setting the SG switch to OFF. The filament switch remains "ON" at all times. The "Xverter" requires a driver tube 10 meter signal in transmit and if the driver tube is turned OFF (Heater switch set to OFF) then there will be no RF signal being applied to the Xverter in transmit resulting in no RF output to the Xverter to mix with the Xverter's transmit local oscillator which results in no RF output from the Xverter.

Joe,

For reading the audio voltages in DB, the meter should have a input impedance of 600 ohms, because this kind of measurements are done with a 600 ohm source. 600 ohms is a norm just as 50 ohms is used for RF voltage measurement.

0db = 775mv/600 ohm.

Nearly all VTVM's have a input impedance of 11 Megohm, too high for a calibrated audio measurement.
Putting a 600 ohm resistor on the input of the meter brings the input impedance down to nearly 600 ohms.

It suffices for a quick measurement of the audio voltages when you align your transceiver.

I hope this answers your question.

"Wim" :

What in heck is the 'accessory socket', and where is it located?

Without knowing, it sounds like a messy unsoldering job. If so, the meter method is far to be preferred.

Morning Dick,

I suspect Wim is referring to the ACC Socket on the Yaesu FT-101. The FT-101's final tube filaments are routed through pins 1 and 2 of the rear panel ACC Socket in the FT-101. Pins 1 and 2 must be shorted with a shorting plug or wire in order for filament voltage to be applied to the final tubes.

Kenwood hybrids do not have their filaments routed through a rear panel Remote or ACC socket. The filament voltage to the driver and both final tubes is routed through the "Heater" switch. Therefore, turning the Heater switch OFF removes filament voltage to the driver and both final tubes.

Hi Dick,
On the ts-830 you use the SG switch, on the Yaesu's FT101zd/901dm you use the accessory socket.
I just mixed things up.
see the previous posts.

Matter closed.

This is not correct! Audio VTVMs read AC volts correctly no matter what the load impedance is. They also read DBs correctly.

It's DBM that requires a 600 ohm load. And the meter measures the voltage across the load just like any other VTVM.

Amazing? Back in the day.... We all operated that way. Novice license, regenerative receiver, Homebrew 807 tube osc/amp, 2 maybe 3 crystals to cover the 40 and 15 meter bands. You called CQ and tuned the whole band hoping to hear your callsign. Nobody thought it strange or amazing back then, why should they now?

In those days we used unrepentant receivers and transmitters. In the 70's
the move was to transceivers. And then Novices were allowed VFOs!

There are still some of us that do work the old way except we may have more
crystals.

But a transmitter like a DX-60 only has 5 crystal sockets and they are only
accessible from the back. So I don't change them very often.

What is "amazing" to me, is that we no LONGER HAVE to operate in that manner. I would think that people would have the ability to match the incoming signal with their sidetone. That is how most modern transceivers operate, isn't it? I can understand someone being somewhere up to 100 hz off the other station, but 500 is a bit of a stretch, unless the separation is intentional !

I cannot understand why modern rigs are not equipped with a "spotting" switch. Almost all older ones did. One would have to be almost tone deaf NOT to be able to tell the difference between the received staion's tone, and one put out by the spotting switch.

I believe the art of "zero-beating" is yet another one of those skills that is disappearing.

Guys,want to thank everyone for their inputs regarding neutralisation. Mike (W5RKL) clearly came out on top with his explanation and detailed info regarding power/plate current/HV calculation too and its been a great period of learning for me. A beer all round for you learned gentlemen. What we gonna do when you guys aren't around to furnish us youngsters with detailed valve operational info ? It would be great to get down on paper all the very much needed information relating to day to day operating of these aged hybrids and I may just take that on. It will, of course, mean that I may bug you for the stuff I don't yet know or understand. Many grateful thanks once again

Hi Dick,

On the ts-830 you use the SG switch, on the Yaesu's FT101zd/901dm you use the accessory socket.

I just mixed things up.

see the previous posts.

Matter closed.

There are still people operating old independent transmitters and receivers
like a DX-60/HR-10 combo.

What irritates me is people using transceivers that don't know how to use
RIT! Every time they come back their frequency has changed!

30027. Re: [TS-520_820_530_830] PLATE CURRENT VERSUS OUTPUT POWER

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-03-01 01:51:14 UTC
From: John Davidson
Topic: 29989 Message: 30027

My TS520 has a very similar PA section and I have no trouble getting 100 W CW output with 200 MA on all bands except 10M.
I have had 825 V on the HV meter with no load since the rig was new. Your current reading seems quite high for the output stated.

From: Will <gm0hks@...>
To: TS-520_820_530_830@yahoogroups.com
Sent: Sun, February 27, 2011 10:08:51 AM
Subject: [TS-520_820_530_830] PLATE CURRENT VERSUS OUTPUT POWER

Is there a reasonable mean average/relationship between plate current and power output with regard to the TS830s. I should be able to calculate I2R, P=VxI etc but what I think I am trying to say is that I would like to establish if my rig is operating within safe parameters for example, on 40 metres with an output power of 60 watts my IP reading is 210ma and at 100 watts it readings 270ma. Is this around the norm or does the plate current seem a little high ?

regards

Will

Hi all,

I couldn't post this to the group as it's 2MB in a zip file, so I have

hosted it on my www.ft-2000.com website.

You can download the file here:

http://www.ft-2000.com/RFVTM.zip

If you want to download the file from a web browser, please ensure that the

RFVTM portion of the url is in UPPERCASE, as it's hosted on a unix server

and therefore case-sensitive.

As mentioned in a previous email to the group, this is not an older Vacum

Tube variety, but a very accurate, modern, RF VTM that is easy to build and

use which helps tremendously with aligning your HF hybrid rigs. - Great for

neutralization and general alignment.

Lastly, just to mention that this is not my design, it is from a VK ham.

Thanks

Chris Parnell, ZL1CDP

30031. Re: TS-830S Low Output 17m SOLVED

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-03-01 06:29:39 UTC
From: k7zs
Topic: 29933 Message: 30031

A special THANKS to Bill, K5GCW, who passed along his experience with the same problem (low output on one band only) and oddly enough also on the 17m band.

Bill recommended I check the inline choke, L36, a 470 microhenry choke in the Driver tube plate line, located on the RF board. He found that the value had changed, and apparently it became resonant around the 17m frequency. Replacing that part, along with a .01 bypass capacitor restored normal operation.

So, I pull the radio apart, removed L36 and used my AADE LCII L/C Meter (a FANTASTIC tool, by the way!). Well, it was still an inductor, but the reading was only about 6 NANOhenries, certainly not 470 MICROhenries. I only had an 800 microhenry molded choke to try, but what the heck, there was NO choke in line before. I put it back in place and fired it up.

SURE ENOUGH! The 17m band DRIVE coil now peaked up normally in the alignment process, and the power output is the same as the other low bands.

Apparently the fault that brought the radio to me, was a shorted driver tube, with enough current drawn to open the inline resistor on the IF board, a 2 watt unit, and this event also took out that teeny little choke it would seem. Nothing visually would indicate it was bad, and it was not open - just way off value.

I will have the exact replacement choke in a couple of days (THANKS to another Yahoo Groups reader) and this TS-830 will re-enter daily service, hopefully for another 30 years!

73 Kevin K7ZS

Hello to all in the group. I have one of my 830s that has a lower receive than the others, S9 on all the others will be about S1 on it. I know it is in the IF board, I replaced the IF board with a spare one I had and now all is fine. Does anyone know if there is a common (most likey component failure on this board)? Thanks for your time hope everyone has a great day!

Hi Ken,

Did you try putting the old IF Unit board back into the 830, cleaning the pins and plugs to see if it works? The RIF signal from the RF Unit board is applied through IF Unit plug 6 pin 6. If that plug and pins are dirty and are not making good connection then the signal level will be less possibly resulting in similar symptoms.

Hello Mike, thanks for your time! Yes I did clean the plugs and pins (deoxit)in & out several times before replacing the IF board. I also did the mod 6.18 in the survival guide. I did check voltages Q1 thru Q8 IF board all seem to be in the range as per the schematic. I was hoping that maybe some common problem with these boards that would be a quick fix. I can always buy another IF board but this one, I would like to find the problem!

Will,

Are you sure that the "meter" is accurate? Measure the the 4 20 ohm

resistors on the final board. You do not have to remove the board to test. They

should be no more than 6 ohms to ground(20% tolerance), the closer to 5 ohms to

ground the better. The higher the ohms, the more the Ip reads and the lower the

power. If I remember right, these affect plate current metering. Find an X-RAY

view of the final board to locate the resistors in question. Check out

n6wk.com and the high-rez service manual. My 830S & 820S will usually put out a

full 100 watts on all bands (except 10 meters) with 220 - 240 mA of Ip. Also,

don't trust the meter on the front to be accurate reading the HV. Measure at the

HV caps or the "800" terminal on the rectifier board. I have seen meters be of

by as much as 90v due to out of value resistors in the metering circuit.

Good luck.....

Subject: RE: [TS-520_820_530_830] PLATE CURRENT VERSUS OUTPUT POWER

I get 90 watts at 200ma and 105 watts at 230ma on 40mtrs.

More plate current does not get me more power out, so 230ma is about max on 40 for this 830.

Bob/W6JZR

Subject: [TS-520_820_530_830] PLATE CURRENT VERSUS OUTPUT POWER

Is there a reasonable mean average/relationship between plate current and power output with regard to the TS830s. I should be able to calculate I2R, P=VxI etc but what I think I am trying to say is that I would like to establish if my rig is operating within safe parameters for example, on 40 metres with an output power of 60 watts my IP reading is 210ma and at 100 watts it readings 270ma. Is this around the norm or does the plate current seem a little high ?

regards

Will

Recently I have taken an interest in buying a TS-520.

I have a set of Benton Harbor S-Line Twins and a set of Drake 4 Twins. So I am familiar with this kind of equipment.

I am interested in the TS-520 because it does not have solid state finals.

What should I know when buying one of these units?

Topic: 30038 Message: 30039

Well, 1st of all, I can tell you from my experience of haning one, that they're just a really nice radio! (guess that's kinda general.)

Like you, I like the fact that it has valve outputs (and a valve driver too). I think it's a hallmark tranceiver, as I think many here will attest to that.

I have a TS-520SE and an Icom IC-718, of which I believe the 520 out performes the 718. The 718 certainly is not a bad radio either; but I've found that the 520 has lower IMD products for 1, and it seems to have a better sounding front end. The only downside I can think of, is that it does not have AM and it does not have a digital readout. Other than that, it's a breeze to operate and to tune up.

Also, as I understand it, you're only sposed to used the 6146B tubes in it -NOT the other type 6146's. Someone may correct me on this, but that's the way I understand it.

Just make sure the 1 yer think'n bout buy'n hasn't been butchered up, and that it's in good shape. I know this user group is a great resource for fixing 'em when they're broke. ;-D

Good morning Bob,

There are 4 different models of Kenwood hybrids, TS-520 (3 versions), TS-820, TS-820S, TS-530S, and TS-830S.

For details on each one I recommend downloading each model's operating manuals at Gordon's website www.n6wk.com/kenwood/ for details.

If you have any questions about the different models please feel free to ask.

I could not afford all this GOOD STUFF when I was young. Now due mostly to eBay I am able to afford a lot of it but I am running out of space to put it.

At the present time I do not have a HF transceiver but I would like to try one.

I live in a 20X20 (400sqft) RETIREMENT CLOSET!

I have a mint condition 520S and I love it. I think everyone should have one of these on their desk just for nostalgia's sake. I was given a 530S that needs restored, and when Gordon is finished working his magic, I will have a desk full of hybrid goodness :)

Hello Jeff,

I mean no disrespect in my response below.

If you have a 50 ohm dummy load or have access to one and a watt meter, you might consider building the simple circuit and connecting it to your transceiver as shown on the diagram so you can see first hand for yourself how well it works.

Bob:
As Mike points out, there are 4 basically different hybrid models. But, be aware, depending on where you are shopping, several of these models may be offered with a different suffix and slightly different features. i.e. the TS-530 can show up as a 530S, or 530SP, or a 530D. The 830 can show up as a 830S or a 830M (has the AM mode with a 6 KHz filter). Another set of Kenwood hybrids, although not a transceiver, is the 599 series of separate receiver/transmitter combos. If you see a model up for sale that perks your interest, a quick Google can probably shed some light on its over all features, performance, accessories, etc. or ask the question here.

Mike,

Thanks for the reply,
I have brought the necessary POT and Battery connector to build the circuit.

Only have to find a suitable container and get one of the full Lic holders at the club to fit for me.

I will take ithe radio to the club and get it properly tested , to ensure that all is working as it should..
Cheer,

Greetings group!

Have 820S. Digital display inop/erratic. Cleaned connector on counter unit and slide contact inside VFO. Display works as it should. But have a problem that I have not seen before:
The display reads correct frequency in receive but, when the send/rcv switch is put to send this is what occurs: 1.8, 3.5, and 7.0 will read 9.000.0Mhz, 14 will read 19.000.0 Mhz, 21Mhz and up will read 29.000.0 Mhz. If have seen this in receive mode on other rigs, but not in transmit. I am a bit confused by the troubleshooting flfow chard in the service manual. ANY help as usual, is appreciated!

Hi Joe,

You said you cleaned the connector on the counter unit. Are you talking about the multiple pins on the top of the Counter Unit, the pins that connect through a plug to the display tubes behind the front panel to the Counter Unit? If so then there are additional connections on the bottom and inside the Counter Unit.

The Counter Unit has 2 boards inside the metal enclosure that are connected together with fixed pins mounted inside the metal enclosure. You have to remove the Counter Unit from the 820, take the outer metal cover OFF, then remove each board, one at a time, and clean the fixed pins on the metal bracket and clean the sockets on the boards. Next, clean the pins on the bottom of the Counter Unit. Once you have done all that, put the Counter Unit back together and install it back in the 820, connect the top and bottom plugs, and test for proper operation.

I picked up a TS-820S at a good price because it had a few problems. The VFO coil spring between the gears came loose somehow and was making the dial feel like it was hitting a bump or binding in a couple of spots. I have the knob, brass and aluminum bushings out and other parts out until I found the spring. It is # 4 on page 37 of the TS-820 service manual. If you have ever seen this spring then you know my problem. What is the trick or easy way to put the spring back on and reassemble the VFO without the spring falling out in the process. I'm having trouble putting the spring in place and trying to put the first gear back in place with out the spring falling down.
Also once or if ever I get this done correctly, do I rotate the gear to tighten the spring like winding a clock, or just leave it unwound.
Thank you in advance for your help. N4MCY

Hi Joe,

No problem, we all tend to forget now and then.

I wouldn't soak the boards in a DeoXit bath. Use a Q'Tip wet with contact cleaner, rub the Q'Tip on the pins and press the Q'Tip on the board sockets where the pin slide into. Then install and remove the board a few times. This provides "scrubbing" action between the board sockets and the pins, cleaning the sockets and pin. Use canned air to remove any/all cleaner residue then install the board back onto the pin and secure it with the mounting screws. Repeat this process with the other board. Put the metal cover back on the Counter Unit and install the Counter Unit back into the 820 and secure it to the chassis with the mounting screws and plug the bottom and top plug back into the Counter Unit and test for proper operation.

Mike & group,

Again, poor choice of words..."bath." The pins/connectors in question were cleaned as stated below...I had high hopes..but alas..no change. Some further info: this problem happens when mode switch is in the CW or FSK posit. and the send switch is in" send." When mode switch is in the USB/LSB posit and the switch is in the send posit..or keyed with a mic connected...no change of displayed freq. So..I have no clue....counter unit?.....PLL/VCO unit...or ? I am not the sharpest pencil in the diagnostic box...so please don't worry about any disrespect. Tnx!

Hi Pete...
... and Bob,

I have the 599 Twins. They do function together as a transceiver depending on whether you connect the transceive cable and set the switches for transceive operation. Even with the cable connected they can still be used as a separate transmitter and receiver. Either piece can be used with any other transmitter or receiver as "separates" - that is, they can stand on their own.

A set of twins is going to take up a little more space on your desk as far as my own memory serves and that might be critical in your retirement closet. It might be like having one of the newer transceivers with an external VFO and maybe external speaker as for desktop real estate.

I think a 520 would serve you very well.

73,

Bill KU8H

I'm seeing a significant number of 520s, 530s, 820s, and 830s listed on eBay. But I have not seen 599s very often.

Right now I am looking for a 520 for $300 or less.

The 599 twins are pretty scarce. I see them from time to time on qth.com's classified section. A ham friend of mine who I have known since I was 18 found an R599A for me in Seattle Washington. I paid $150 for it and it has the 6 and 2 meter converters plus all the filters. It has a warble problem that needs to be fixed. I have narrowed the problem down to the VFO. One of these days I'll pull the VFO and find out what's causing the problem and fix it. I hope one day to find a T599A to match up with this R599A. Not in a hurry to find the transmitter.

The 520/530/820/830 sold here in the U.S. are classic SSB/CW type rigs so there's lots of them around. The 830 was especially popular as a workhorse contesting and DX rig. Many of these models also found there way into the hands of CB operators. The 599 Twins are unique in that, besides being a SSB/CW rig, it also had the AM mode. When transmitting in the AM mode, it was hard to distinguish it from a plate modulated rig on the air. The receiver selectivity control for controlling the filters could be set to automatic and would choose the correct filter when changing modes or you could manually set the filters (from .5 Khz to 25 KHz). The receiver even has a squelch control that operates in all modes and can also receive FM. Great noise blanker and even the analog dial is accurate. Great receiver/transmitter combination that for me, never lose their appeal.

30061. VFO-820 tuning knob replacement

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-03-04 19:55:30 UTC

I've been fortunate enough to come by a decently priced VFO-820. Of course, in return for the decent price, it has a few warts. The worst is the tuning knob, which has a big ding in the nice shiney center. Does anyone know where I might obtain an undinged knob? Thanks.

Drop Bob Mansker, ke5ftf, an e-mail (ke5ftf at mail.com). He may be able to help you.

Ken, K4EAA, sells a very nice weighted replacement knob, see his website for details

www.k4eaa.com

Mike & group,

Again, poor choice of words..."bath." The pins/connectors in question were cleaned as stated below...I had high hopes..but alas..no change. Some further info: this problem happens when mode switch is in the CW or FSK posit. and the send switch is in" send." When mode switch is in the USB/LSB posit and the switch is in the send posit..or keyed with a mic connected...no change of displayed freq. So..I have no clue....counter unit?.....PLL/VCO unit...or ? I am

not the sharpest pencil in the diagnostic box...so please don't worry about any disrespect. Tnx!

Hi Joe,

No problem, we all tend to forget now and then.

I wouldn't soak the boards in a DeoXit bath. Use a Q'Tip wet with contact cleaner, rub the Q'Tip on the pins and press the Q'Tip on the board sockets where the pin slide into. Then install and remove the board a few times. This provides "scrubbing" action between the board sockets and the pins, cleaning the

sockets and pin. Use canned air to remove any/all cleaner residue then install the board back onto the pin and secure it with the mounting screws. Repeat this process with the other board. Put the metal cover back on the Counter Unit and install the Counter Unit back into the 820 and secure it to the chassis with the

mounting screws and plug the bottom and top plug back into the Counter Unit and test for proper operation.

Joe,

Have you checked the Counter Unit's standard oscillator frequency? The formal check and adjustment is on page 49 at the top left of the page. A frequency counter is required to perform the formal adjustment which I believe is more accurate than the WWV adjustment on page 48.

Mike & group,

Did check as stated on pg 49 of service manual. Freq is exactly 1.000.00Mhz. I just don't know where else to look. The receive frequency tracks along with the VFO(indicated) digital frequency. As stated prior, "9.000" 19.000, or "29.000" only come up when rig in CW/FSK and switch is in send or, if in USB/LSB with mic connected and "keyed" . HELP!!!

30069. Tune up issues with old TS-530S

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-03-05 13:24:00 UTC
From: John Hennessy
Topic: 30069 Message: 30069

Hi, I am fortunate to have two of these, a perfect condition one and a not so good one. The not so good one is not tuning up correctly up even thought the same procedure tunes the good radio properly. I have followed the manual and Kens (K4EAA) tune-up procedure to the letter but as soon as I dip the plate in CW mode I get odd results. As I'm adjusting the plate current can jump up to around 300mA and if it does I can't adjust it any lower. Returning to Rec and waiting a moment seems to give me another go at dipping the plate. Any attempt to load even a little result in current reading of 300mA. Output power is at 100W but shouldn't I be able to achieve this with 225mA?

Could it simply be a dummy load problem failing under high output power. I am being quick to tune up. I have also tried tuning against a resonant antenna (antenna close to resonance + tuner = resonant) and still see the same problem.

Any assistance would be much appreciated.

thanks

John.

Hi John,

I would check the plate tuning capacitor, ensuring that the rotating vanes are indeed grounded throughout the entire rotation, and I would definitely check the PA neutralization, the latter being the most likely cause.

Also ensure that you have 6146Bs installed, not the A ...

Regards

Adrian - ZS1TTZ

Joe:

Perhaps you have already described all the symptoms of the radio, but does it transmit Okay? As on the right frequency?

From: kj4fcj
Topic: 30072 Message: 30072

Hi everyone, I need to know the detailed. Tuning procedure for using an 811 with my 820s for ssb operation. I do know how to tune the 820s but, I know the amp is different,& the manual doesn't help. I know they have videos for this but, they are using a modern rig and adjusting the input drive(as far as I know) is a different ballgame. I'm sure its a very simple process to do right. Any help, is greatly appreciated. Charles Kj4fcj

Robert,

Short answer....NO. Once the rig is placed in "send" and the digital frequency readout indicates the "9.000"...etc...no further operations are possible, except I can obtain 60mA of Ip. From reading the service manual, this is a stated problem...I have seen it before in receive..but NOT transmit. I am loosing what little hair I have left. I have limited diagnostic knowledge.. and equipment...but trying to get better...

Hello John,

The PLATE control is set within the PLATE control arc silk screen indication based on the band switch setting. Furthermore, the LOAD control is set to maximum capacitance, meaning the LOAD knob points to 9 o'clock. Both controls, PLATE and LOAD, are set as described above before starting the tune up procedures regardless of the band.

Please provide information for the following:

1. You can achieve a good and stable ALC peak indication in TUNE mode, meaning the meter switch is set to ALC and adjusting the "DRIVE" control results in a peak indication. Is this true?

2. When adjusting the PLATE control, with the meter switch set to "IP", there is very little, if any, "dip" in IP current. Is that true

Again, please let us know the answers to both 1 and 2.

Mike & group,

Did check as stated on pg 49 of service manual. Freq is exactly 1.000.00Mhz. I just don't know where else to look. The receive frequency tracks along with the VFO(indicated) digital frequency. As stated prior, "9.000" 19.000, or "29.000" only come up when rig in CW/FSK and switch is in send or, if in USB/LSB

with mic connected and "keyed" . HELP!!!

Joe,

Have you checked the Counter Unit's standard oscillator frequency? The formal check and adjustment is on page 49 at the top left of the page. A frequency counter is required to perform the formal adjustment which I believe is more

accurate than the WWV adjustment on page 48.

Okay, with those symptoms it is not just the display unit.

Since you have already swapped out the VCO/PD unit (I assume you removed and replaced the whole module; they are two boards in that can, the top one for the VCO and the bottom one for the PD) the next thing that comes to mind is the carrier unit.

If the carrier unit failed to produce the required signal in transmit that would cause a problem. It may even be that the carrier unit is working but fails to produce a signal level high enough for transmit.

Now, the 820S manual has some errors with respect to the carrier unit. They got confused as to what board they were talking about. I suggest you go over to Mods.DK and download the rewritten alignment procedure they have there - it has the correct data for the carrier unit alignment as well as some additional data not incdued in the manual - and the whole thing reads easier, too. By the way, there are multiple additional alignment instructions on that website - be sure to download the larger one, not the newest one posted.

You say you have a frequency counter. That will do for setting the freq on the carrier boards, but it is best to have an oscilloscope to set the output levels. Otherwise you could use an RF probe with a VTVM or digital VOM.

Check the carrier signal at the input to the IF board, using the freq counter when the rig is in Receive mode and when it is in transmit mode It is on the IF board way up toward the front of the rig, back near where the connectors for the IF board are. You can best get to it by looking under the board with the rig sitting upright on its right side. Obviously, do this with the SG switch "off."

If the carrier signal goes away in transmit in any or all modes mode then you have found the problem.

It is relatively easy to remove the carrier unit and take the boards out of it so you can clean the contacts and do repairs. The bottom board on the carrier unit uses a tantalum capacitor and they are notorious for going bad. There is an article on Mods.DK about changing out that cap in order to fix a frequency instability problem with the carrier unit. I suppose if the cap went really bad it might take out the board entirely, but I have not looked at the schematic to see.

Of course a loose or bad connection on the connector to the carrier unit will cause problems too. The connectors on the TS-820S beat anything I have ever seen when it comes to their propensity to fall off and cause problems. A partial conenction can cause truly weird stuff, some of which is catastrophic to the finals.

Good luck and let us know what you find!

Afternoon Joe,

Based on your new information, loss of transmitter output, no RF output etc in transmit, the carrier signal is missing in transmit.

First, check for the presence of 9VDC on CAR UNIT plug CJ2 pin 6 in transmit. It doesn't matter what mode.

If the 9VDC is missing, check the Relay Unit plug RL2 pin 13 for 9VDC in transmit. If 9VDC is missing or very low, pull the relay from the Relay Unit, remove the plastic cover, and gently cleaning the relay contacts with contact cleaner.

The problem could also be caused by too low of a CAR UNIT signal, see page 45 in the 820 service manual, "CARRIER UNIT ADJUSTMENT", 2-1. The CAR UNIT output signal level should be adjusted for an output level as measured at the CAR UNIT Plug CJ3 pins 2 and 5 on page 58 of the 820 service manual.

Mike(w5rkl) & Robert(wb5wsv),

Mike, I was thinking about that relay. All seems well until, rig in send. I will do that check/clean. I have a known good relay that I can sub. Also, I'll do that testing that both you and robert suggest. Tnx fer all the assistance! Keep ya posted.....

30079. 830 Warc Mod

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-03-05 23:22:18 UTC
From: Chris Parnell
Topic: 30079 Message: 30079

Hi all,

Just a quick question. - Aside from removing the blue wire from Pin 4, connector 6 on the AF board in order to open up WARC bands on the 830s, is there another way to obtain this?

The only reason I ask is that I purchased a RF board and fitted it to my 830s, and there was a note saying "No WARC mod done" on the RF board. - Of course, it doesn't transmit on the WARC bands, but I wondered what was different on the RF board with this one to my previous RF board that had WARC enabled (hope this makes sense)☐.

In other words I didn't have to remove blue wire from AF board previously.

Thanks in advance.

Chris,

Look at the owner's manual, Pg 27, Section 5.5 "TRANSMITTING ON WARC BANDS" bottom right corner. There are some diodes you can cut to activate individual WARC bands on the RF board. However, it's easier just to cut the wire. Good luck.....

Thanks Joe,

Makes sense (D4, D5 and D6)... But oddly enough, just checked the old RF board and they have not been cut! ;-) very strange.

Anyway, pulled the blue wire from it's socket and all fine.

Cheers... Chris, ZL1CDP

K4EAA has sold out of his repro K1 knobs, and apparently isn't anticipating producing any more. Darn shame; they were very nice indeed.

I'll try the other suggestions from you and the rest. If I find a source, I'll post it "for the record".

Bill

Mike & Robert,

9.0V obtained on CAR UNIT plug CJ2 pin 6 in transmit. 9.0V on RL2 pin 13. In the CAR UNIT adjustment on pg 45, could not obtain proper voltage level regarding T-1 on CAR-2 (50mV). Dug around in parts bin and found CAR UNIT and subed that. Adjusted voltages to specs. Digital display now reads as it should(but it's still about 1Khz high). I think I'll let it run tonight and adjust to specs tomorrow. What an experience that was! TNX Mike & Robert for your guidance! I'll keep you & the group up on this.

Mike(w5rkl) & Robert(wb5wsv),

Mike, I was thinking about that relay. All seems well until, rig in send. I will do that check/clean. I have a known good relay that I can sub. Also, I'll do that testing that both you and robert suggest. Tnx fer all the assistance! Keep ya posted.....

Subject: [TS-520_820_530_830] Re: 820S freq. readout

Afternoon Joe,

Based on your new information, loss of transmitter output, no RF output etc in transmit, the carrier signal is missing in transmit.

First, check for the presence of 9VDC on CAR UNIT plug CJ2 pin 6 in transmit. It

doesn't matter what mode.

If the 9VDC is missing, check the Relay Unit plug RL2 pin 13 for 9VDC in transmit. If 9VDC is missing or very low, pull the relay from the Relay Unit, remove the plastic cover, and gently cleaning the relay contacts with contact cleaner.

The problem could also be caused by too low of a CAR UNIT signal, see page 45 in

the 820 service manual, "CARRIER UNIT ADJUSTMENT", 2-1. The CAR UNIT output signal level should be adjusted for an output level as measured at the CAR UNIT Plug CJ3 pins 2 and 5 on page 58 of the 820 service manual.

73s
Mike

Joe,
I have found on many of the TS-820 radios that the little spring contact clips inside the plastic connectors break.
They look fine from the outside, but do not make contact with the pins when the connector is plugged on to the boards.
I have chased my tail a few times because of this and it has only been on the TS-820 radios for some reason.
Hope it might help you.

30085. No transmit output power on 830s

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-03-06 04:50:39 UTC
From: Chris Parnell
Topic: 30085 Message: 30085

Hi all,

Having replaced the RF unit on my 830s, and after a few problems I have the receive working very well now.
There is current on the IP meter when heater is on at 60mA and all seems ok, except I have no actual output power at all (on either RF meter on 830, or external power meter).

I can hear a signal (reads around S7) on another receiver in the shack)☐
It's not the tubes as I have changed them, so I am beginning to look elsewhere and am suspecting that there is still an issue in the rectifier unit. (I blew R14 previously).

Any help on letting me know what to test for voltage wise in the rectifier unit would be much appreciated.

Thanks
Chris, ZL1CDP

Hey Gordon,

I was wondering where you had gotten too. I hope that you are continuing to feel great. I inspected those pesky connectors under HIGH magnification and really bright light and found them ok. I made up a dummy pin connector that I can plug in to a connector in question and run a continuity check that way. The CAR UNIT that I put in(found in parts box) is working FB. Part of the original one failed. Will finish checking the rest out tomorrow. This has been a real good exercise for me. Just kind of frustrating sometimes.....

Hi Adrian, thanks for your reply. Can you please provide a little more detail as to how I check the grounding through the tuning rotation. I will read a little more to try and understand how I check the PA neutralization, this is new to me. Next time I have the radio open I will check the tubes. Having said that the radio is all original so I'd expect original valves.

John.

Hi Mike, thanks for your reply. initial settings are as you've described in your first paragraph.

1. Yes I get a peak reading that is exactly vertical with a carrier control set to 1/2 way (12 oclock). Although twitching twice while adjusting upwards I do arrive at an obvious and stable peak. The twitching is a sudden drop backwards followed by forward in response to further turning of the drive control clockwise. This always happens twice in the same position on the adjustment.

2. The IP reading is around 125mA at the top of the silk-screened 7m band scale and dips to 90mA when adjusted.

Thanks for all the help received so far. I'm looking forward to fixing this one.

Hello John and Adrian,

I do not believe the final tubes, "A" verses "B", is the source of your problem.

When comparing inter-electrode capacitance differences between the 6146A and 6146B, the only inter-electrode capacitance difference is the Grid #1 to Plate capacitance which is ".24pf" in the 6146A and ".22pf" in the 6146B. All the other inter-electrode capacitance values are the same in the 6146A and 6146B. A difference of ".02pfd" (.24 - .22 = .02) when operating the final amplifier in the HF spectrum is not a "significant" difference that warrants using only 6146Bs in the hybrids. If the final amplifier were to be operating in the VHF spectrum then I would be concerned but that's not the case with the hybrids. When using "A" verses "B" tubes, neutralizing the final amplifier is required.

The final amplifier's neutralization adjustment does not drift or change due to tube age.

I am aware of and have read Glen Zook's "The 6146 Family of Tubes" document in the files section.

John, what position do you set the LOAD control when you start your tune up procedure? I recommend setting the LOAD control fully CCW (knob points to 9 o'clock) then start your tune up procedures, peak ALC then dip the plate. Once you are at this point, advance the LOAD control CW for a peak RF output and watch the IP meter while adjusting the LOAD control. If the IP meter erratically jumps higher, not in a smooth fashion, the I suspect the fixed and variable plates are shorting due to corrosion, dirt, or the plates themselves are shorting.

Joe:

The 50MV spec in the manual is WRONG!

Correct carrier module output should be 0.30 V - SIX times higher!

And in the manual they are wrong when they say which adjustment to use for what.

Here is the correct procedure:

Connect a freq counter to either pin 7 of socket Cj3 or to the carrier input on the IF board.

Set the mode switch to LSB and the IF-shift control to its center position.

NOTE: The USB and LSB board, CAR-1, is ON THE BOTTOM of the module. You have to reach down through the holes in the top board, which is the CW transmit board, CAR-2, in order to get to the USB and LSB adjustments.

Adjust TC1 to 8828.5 KHZ within 10 Hz (its hard to do this, I know, the adjustment is pretty twitchy so just get as close as you can). It will help a lot if you can find a nonmetallic screwdriver with which to do this. Me, I am still looking for one that will work; the plastic ones I have are all too flimsy. And the metal ones affect the frequency.

Switch the mode switch to USB and adjust TC2 to 8831.5 KHZ within 10 hz.

Adjust T1 on the bottom board, CAR-1, to an output level of 0.3V or as high as you can get it. It probably won't go much over 0.3V in any case.

Switch to transmit (SG Switch Off) and put the transmit switch in Send position and adjust VR1 on the CAR-1 board so that the frequency for USB and LSB transmit does not change between receive and transmit.

Switch to CW mode. With the transmit switch in Send adjust TC-1 on the CAR-1 board, the board on top, to 8830.7 khz and adjust coil T1 on the CAR-1 board to get 0.3 V output.

The other two adjustments on the CAR 1 board, TC2 and TC3, are for adjusting the FSK frequencies in case you are interested.

I hope this makes sense to you. Given the errors in the manual and omissions in other sources it took me a while and some technical help from people like Mike help to figure all of this out.

Hello Joe and Robert,

I believe the "50mv" signal level is only a starting point signal level even though Kenwood's 820 service manual does not state this. When I make that adjustment, I ignore the reference to CAR1 T1 but rather adjust T1 on CAR2 for a reading on TP5 on the IF Unit.

I also believe step 2-1 that states to adjust T1 on the "CAR1" board while measuring the voltage level at TP5 on the IF Unit is wrong.

To see this you have to look at the main 820 schematic along with the IF Unit and CAR Unit schematics.

The output from CAR1 is applied to the balance detector from CAR UNIT plug CJ3 pin 5, through the wiring harness, to the IF Unit plug IF4 pin 2 labeled "C1A". This provides the required "BFO" signal, in "receive", that beats with the IF signal on the IF UNIT to produce the "recovered" audio at the output of the balance detector. If you follow the CAR1 output signal to the IF Unit board then look at the schematic of the IF UNIT board you will see how this takes place. Furthermore, if you follow the output from the balance detector through plug IF4 you will see the balance detector's recovered audio is applied through the wiring hardness to the AF AVR Unit for further processing and ultimately to the audio amplifier and finally the speaker.

Next, if you look at the CAR UNIT schematic, you will notice that both CAR1 and CAR2 have a transformer labeled "T1". However, if you follow the output from CAR2, through the main 820 schematic, you will notice CAR2 output is applied to the IF UNIT plug IF5 pin 13 which, through the IF UNIT board's foil connection, connects directly to IF Unit "TP5". Therefore, step 2-1 that refers to adjusting T1 on CAR1 board is wrong. What the step should say is adjust T1 on "CAR2" for a voltage measurement found at TP5 on the IF Unit board.

The correct voltage level is not 50mv but rather ".3 volt" or "300 milli-volts" at CAR UNIT plug CJ3 pins 2 and 5 as shown on the CAR UNIT schematic on page 58.

If the CAR UNIT output signal levels are much lower than required, it is quite possible switching from receive to transmit can and will cause the symptoms you are experiencing where the digital display appears to work fine in receive but in transmit the digital display shows 9,000, 19,000, and 29,000 in transmit. Therefore, I recommend you adjust the CAR UNIT output signals so they are .3 volt at CJ3 pins 2 and 5 and not 50mv at stated in step 2-1.

One additional comment about the CAR UNIT output signal level. When adjusting CAR1 and CAR2 for .3 volt rms at CJ3 pins 2 and 5, note that CJ3 pin 7 has a ".2 volt rms" signal level. Pins 5 and 7 are from CAR1 and you adjust T1 on CAR1 for a signal level of .3 volt rms at pin 5 which will result in a .2 volt rms signal level at CJ3 pin 7. Pin 7 is the carrier unit signal that is applied to the PLL Unit and if this level is too low for the PLL Unit to use the symptoms you are experiencing will occur. Therefore, adjust T1 on CAR1 for .3 volt rms at pin 5 and check CJ3 pin 7 for .2 volt rms.

If you perform the adjustments on the CAR UNIT board as described and there are no other problems with the 820 then I suspect your problem will be fixed.

Have been using my 830 for a year ,no problems. Tunes up into the dummy load 100+ out. switch to ssb ,key the mic ,speak the alc meter moves to proper alc scale range and watt meter shows {pep} meter 70-90 watts on peak audio,after a second or two the alc almost sits on the left pin and the watt meter shows maybe 30-50 watts on peak. If I whistle into the mic the alc goes to proper scale as does the watt meter. tried 2 different mic's....same result. any ideas?
thanks

Hi Dale,

I suspect either a weak driver or weak final tubes.

A driver tube that is become weak will show a falling ALC indication during tune up after peaking the ALC meter in TUNE mode. The ALC will peak but the ALC indication will not be stable, the meter will slowly or rapidly, depending how weak the driver tube is, back towards zero in TUNE mode. There should be more than enough RF drive from the driver tube to peg the ALC meter full scale to the right in TUNE mode and that ALC indication should be stable and not drop back towards zero if the driver tube is good.

A weak final tube(s) will initially show full, or almost full RF output when initial tune up occurs. However, as the tubes operate and become warmer, power output will become less even if the peak ALC indication in TUNE mode is stable. A good set of final tubes should produce a stable full power output whether during initial tune up, 10 to 20 minutes of operating, or 1 hour of operation. If power output drops even when the ALC peak is stable in TUNE mode, then the final tubes are getting weak.

Dale,

One additional comment about ALC meter indication in sideband.

The ALC meter, with normal voice levels, does not need to be consistently at mid or full ALC scale.

ALC is the transmitter's "gain control" voltage. Every time ALC is produce (grid current flowing in the final tubes), the gain of the IF stage is "reduced". When the gain of the IF stage is reduced, so is the RF power output of the 830. The final amplifier in the 830, just like the other final amplifiers in other hybrids, operates in Class AB1. Class AB1 amplifiers are not suppose to have grid current flowing at any time during the RF sine wave cycle. When grid current flows in the final tubes then ALC gain control voltage is produced and the ALC gain control voltage is fed back to the "IF" stage to "reduce" the gain of the IF stage. This results in a reduction in driving signal to the final tubes and ultimately lowers the RF output from the final amplifier as long as ALC voltage is present.

Tuning up the MIC gain so you see peak RF output and an ALC meter indication of mid to full ALC scale is not the right way to adjust the MIC gain. When speaking into the microphone at a normal voice level, the MIC gain should be adjusted to the point where the ALC meter just flickers above zero, not consistently at mid to full ALC scale.

It's not how loud you sound on the air but how clean your signal is. When the ALC meter just starts to flicker above zero is the MIC gain setting that is producing maximum RF peak power output. Any further increase in MIC gain will result in further reduction in overall gain in the 830 and can lead to splatter if the MIC gain is turned up too high. The higher the ALC meter display is the more gain reduction occurs in the 830 resulting in a reduction in RF output.

Mike
the alc reading was always about 0 to 1/4" above ,untill now always had reports of clean audio with the 830. Now to see what a new driver tube will do.
thanks

Hi Dale,

I suspect either a weak driver or weak final tubes.

A driver tube that is become weak will show a falling ALC indication during tune up after peaking the ALC meter in TUNE mode. The ALC will peak but the ALC indication will not be stable, the meter will slowly or rapidly, depending how weak the driver tube is, back towards zero in TUNE mode. There should be more than enough RF drive from the driver tube to peg the ALC meter full scale to the right in TUNE mode and that ALC indication should be stable and not drop back towards zero if the driver tube is good.

A weak final tube(s) will initially show full, or almost full RF output when initial tune up occurs. However, as the tubes operate and become warmer, power output will become less even if the peak ALC indication in TUNE mode is stable. A good set of final tubes should produce a stable full power output whether during initial tune up, 10 to 20 minutes of operating, or 1 hour of operation. If power output drops even when the ALC peak is stable in TUNE mode, then the final tubes are getting weak.

Hello all, been a while since I've been on. In the meantime, I've acquired a 530 on fleebay that's seen better days. I have no transmit and no receive. Rig powers up, meter lights up (now that I've changed the bulb!), no ALC, no IP, no RF, HV is around 450 to 500. Some idiot in the past decided to wrap the 6A fuse with aluminum foil when it blew which you can imagine what the rig looks like. I've changed the HV caps, there are burn marks on the rectifier board which I've changed many diodes and resistors, the final board was burned, so I replaced the screen and cathode resistors, I performed the final cage repair that is noted on Ken's (k4eaa) website. So I've done some work, but my troubleshooting ability is poor. I noticed after working on the rectifier board that I lost some HV. I had about 900 before, but was worried about all the fried parts on the board. There was one bad diode, D10 if I remember correctly, and several resistors that were well out of tolerance. I'm not sure where to go next, any help would be greatly appreciated. 73 de AI4NV - Steve

Hello Steve,

Check and make ensure the rear panel "SG" switch is set to "ON".

Next, measure the voltages on the following Rectifier Unit terminals. The voltages on these terminals is "DC" and your volt meter must be set to measure "DC". Your DC volt meter must be capable of measuring at least 1,000VDC. Do not attempt to measure these voltages using a cheap "hardware store" $10 volt meter.

1. 800
2. 300B
3. 210A
4. 210A
5. -C
6. 12

Next, measure the DC voltages at the following final tube socket terminals in receive.

Pin 1
Pin 3
Pin 5

Last, measure the voltage at the top of RF choke "L2". RF Choke "L2" is inside the final amplifier's metal enclosure and is between the 2 final tubes. The top of RF Choke L2 connects to each of the final tube plates through the parasitic suppressors (each parasitic suppressor has a coil wrapped around a resistor and connected between RF Choke L2 and the top plate connector of each tube). The top cover of the final amplifier must be removed to make this measurement. RF Choke "L2" is the tall white cylinder with wire wrapped around it. Measure the voltage at the top of the RF Choke. The voltage at the top of RF Choke L2 should be the same as the voltage measured at the Rectifier Unit's "800" terminal.

Use "extreme caution" when measuring these voltages. There are voltages inside the 530 that can kill you. All voltages are measure between the terminals indicated above and chassis ground. That measure the Red meter lead is connected to each terminal and the Black meter lead is connected to the 530's chassis.

Measure the DC voltages on the AF Unit board at the following terminals and plug pin;

12
TP-4
TP-6
Plug 11 pin 5

The voltages present at the above terminals/plug pins are 12VDC or less. The voltages are measured in receive.

Hi Chris

Congrats on getting the RF board replaced, and getting the radio to receive.

No power out on any band? You might want to ensure the SG switch on the rear apron is ON, and don't take the switch position for granted - measure the voltage on the SG pin of the FINAL UNIT. When the SG switch is OFF, the voltage on PIN 3 of the tubes will me NEGATIVE, perhaps -50v or so. If the SG switch is dirty and not switching to a POSITIVE voltage, that would prevent transmit. In receive, you'll should see around 264v (132v if in mode switch is in the TUNE position). No positive screen voltage, no transmit PERIOD! So, start at the back end and work forwards - sounds like you are getting the proper frequency mixed.

You are certain that the BANDSWITCH WAFERS in the final unit are 'in sync' with the ones on the RF unit. It is possible to get them 180 degrees out of sync. You might get SOME power out on a band here and there, but overall this will prevent much if any output.

Do you get the expected deviation on the meter when tuning, with the meter switch in the ALC position? This indicates the signal is being amplified by the driver tube and delivered to the final unit, closing in on the problem.

Hope this helps, by at least eliminating the 'easy stuff'you'll get closer to the culprit.

Kevin,
I have a VFO-520s that I run with a Ts-520 and it works fine but the description of the functions on the function switch on the Vfo is not really correct. But it wires up, plugs in and works fine once you get used to the switching. I would think it would be the same in your case

Subject: [TS-520_820_530_830] Re: 820S freq. readout

One additional comment about the CAR UNIT output signal level. When adjusting CAR1 and CAR2 for .3 volt rms at CJ3 pins 2 and 5, note that CJ3 pin 7 has a ".2 volt rms" signal level. Pins 5 and 7 are from CAR1 and you adjust T1 on CAR1 for a signal level of .3 volt rms at pin 5 which will result in a .2 volt rms signal level at CJ3 pin 7. Pin 7 is the carrier unit signal that is applied to the PLL Unit and if this level is too low for the PLL Unit to use the symptoms you are experiencing will occur. Therefore, adjust T1 on CAR1 for .3 volt rms at pin 5 and check CJ3 pin 7 for .2 volt rms.

If you perform the adjustments on the CAR UNIT board as described and there are no other problems with the 820 then I suspect your problem will be fixed.

Also check the band switch nylon coupler in the final. I had to replace several as they split at the set screw and the band switch on the front panel didn't always switch the final wafers, ugh.

Also check the band switch nylon coupler in the final. I had to replace several as they split at the set screw and the band switch on the front panel didn't always switch the final wafers, ugh.

Subject: [TS-520_820_530_830] Re: No transmit output power on 830s

Hi Chris

Congrats on getting the RF board replaced, and getting the radio to receive.
No power out on any band? You might want to ensure the SG switch on the
rear apron is ON, and don't take the switch position for granted - measure
the voltage on the SG pin of the FINAL UNIT. When the SG switch is OFF, the
voltage on PIN 3 of the tubes will me NEGATIVE, perhaps -50v or so. If the
SG switch is dirty and not switching to a POSITIVE voltage, that would
prevent transmit. In receive, you'll should see around 264v (132v if in
mode switch is in the TUNE position). No positive screen voltage, no
transmit PERIOD! So, start at the back end and work forwards - sounds like
you are getting the proper frequency mixed.
You are certain that the BANDSWITCH WAFERS in the final unit are 'in sync'
with the ones on the RF unit. It is possible to get them 180 degrees out of
sync. You might get SOME power out on a band here and there, but overall
this will prevent much if any output.
Do you get the expected deviation on the meter when tuning, with the meter
switch in the ALC position? This indicates the signal is being amplified by
the driver tube and delivered to the final unit, closing in on the problem.
Hope this helps, by at least eliminating the 'easy stuff'you'll get closer
to the culprit.

Nylon is OK, if you leave enough meat around the set screw. The point contact of the #4 setscrews is just too flimsy.

Thanks for the suggestions Kevin.

Will do some further testing based on this. - I have some comunique going

with the excellent Mike W5RKL to help trace this fault too, so I am sure we

will get there in the end.

Thanks again

Chris, ZL1CDP

Subject: [TS-520_820_530_830] Re: No transmit output power on 830s

Hi Chris

Congrats on getting the RF board replaced, and getting the radio to receive.
No power out on any band? You might want to ensure the SG switch on the
rear apron is ON, and don't take the switch position for granted - measure
the voltage on the SG pin of the FINAL UNIT. When the SG switch is OFF, the
voltage on PIN 3 of the tubes will me NEGATIVE, perhaps -50v or so. If the
SG switch is dirty and not switching to a POSITIVE voltage, that would
prevent transmit. In receive, you'll should see around 264v (132v if in
mode switch is in the TUNE position). No positive screen voltage, no
transmit PERIOD! So, start at the back end and work forwards - sounds like
you are getting the proper frequency mixed.
You are certain that the BANDSWITCH WAFERS in the final unit are 'in sync'
with the ones on the RF unit. It is possible to get them 180 degrees out of
sync. You might get SOME power out on a band here and there, but overall
this will prevent much if any output.
Do you get the expected deviation on the meter when tuning, with the meter
switch in the ALC position? This indicates the signal is being amplified by
the driver tube and delivered to the final unit, closing in on the problem.
Hope this helps, by at least eliminating the 'easy stuff'you'll get closer
to the culprit.
73 Kevin K7ZS

Hi Mike, LOAD control starts at its lowest CCW setting (9 o'clock). I then peak the ALC and dip the plate as you've stated. The IP meter is jumping erractically while loading also as you've stated. Where exactly are the fixed and variable plates you are speaking of? The radio appears perfectly clean but has sat idle for many years. The rig has also been cleaned out gently with compressed air.

thanks

John.

John,

The variable plates Mike is talking about, I think, are the ones in the "final cage" area..where the final amp tubes are. The are also 3 others connected to the "DRIVE" shaft. Get yourself some DEOXIT or similiar. UNPLUG rig, and let it sit. Remove top and bottom cover. There are...I think 6 screws that hold the cover on. Use an insulated screw driver to short to ground the plate choke...that's the thing with the two caps on it going to the tops of the finals..there is LETHAL VOLTAGE that can lurk in there. The load control is on the left...it has slider contacts..spray(sparingly) the plates and the contacts..work back and forth numerous times..blow off with "canned air." Do the same with the plate control....it.is in the middle. While your in there..remove the finals..and clean the large wafer switch..spray and rotate..blow dry. Inspect the band switch coupler...they crack where the hold-down screws are. And...have some more fun!....remove every connector...one at a time..use DEOXIT as above (remove and replace several times), also every switch, and/or pot. I have "fixed" problems..just by cleaning a rig that has sat around..collecting dust..etc.....good luck

Mike,

Once I was "in there" I took the PLL and CAR boxes out...and opened them up. Well...something had really contaminated both units...maybe "coffee with cream and sugar." Also I found a couple of broken solder traces: one on PLL-1 pin 6 and PLL-1 pin 5. Looks like the connector had really been pushed down hard a few times. Then..somebody had the CAR voltages way off....and some of the tuning slugs on the PLL had also really been messed with. This may have been a poorly "fixed" CB hack. I found some screw holes with no screws...etc. I did a "basic" tune up on the ANT, MIX, and DRIVE coils..etc.. (I do not have the equipment/skill to do a full alignment). It still has the S2001A's in the final cage...screen and cathode R's are original..and within specs....all bands function..with anywhere from 110 to 90 watts into dummy load with 205-230mA of Ip..still has plenty of HV on key down. Had to take XYL to dinner though...hihi..... agn.. TNX fer all the help!

Hi Joe, thanks for getting across this. The 3 variable plates connected to the drive control I'm familiar with. My mention of using compressed air to clean was related to these. To date I have not ventured into the final cage area but am aware of the dangers and precautions with regards discharging. Deoxit I have.

With all that information in hand I'm confident that it will be fixed :-) It will probably take a day or to for me to get back to it but will report back my results then.

thanks again

John.

Hi John,

There are numerous types of variable capacitors.

There are compression type variable capacitors which has a fixed plate that does not move and a plate the moves by adjusting a screw. As the screw rotates CCW or CW the movable plate moves closer to or farther away from the fixed plate.

There are variable capacitors that have fixed plates mounted to a metal frame using insulating material with variable plates mounted to a shaft where the shaft rotates and the variable plates slide between the fixed plates.

There are vacuum variable capacitors where the fixed and movable plates are encased within a vacuum must like a vacuum tube.

When I speak of the fixed and variable plates shorting together in the LOAD variable capacitor, I'm talking about the variable plates, as they slide between the fixed plate, the fixed and variable plates short together.

Shorts can be caused by bent fixed and/or variable plates of the capacitor or dust/dirt/corrosion build up on either the fixed, variable, or both sets of plates.

If the LOAD capacitor is shorted between the fixed and variable plates, an ohm meter connected between the fixed and variable plates will indicate zero ohms.

You can search the Internet using your favorite search engine using the phrase "types of variable capacitors" then click on photos. I use Google and when I search for a component such as variable capacitors, I enter the above phrase and when the results come up, I click on Google's "Image" link on the upper left corner and pictures of variable capacitors will come up.

John,

Compressed air cannot always clean away corrosion. Corrosion "tips" can occur on the plates due to the environment the component is subjected to. Since the radio has sat for a long time, corrosion tips can occur on the fixed and/or variable plates which compressed air can't remove. To remove corrosion you need to use a stiff piece of paper wet with contact cleaner and slide the paper between the plates. This doesn't always work either. It depends on how big the corrosion tips are. If you listen closely in a quite room, while rotating the LOAD control, a shorted variable capacitors will sounds like the fixed and variable plates are scrapping against themselves. You have to listen closely to hear it. I have run into LOAD variable capacitors where a variable plate, only one, was shorting to the fixed plate when the capacitor shaft was rotated only half way. When this happens, all RF is shorted to ground resulting in zero RF output. Rotating the LOAD control CCW a bit caused the shorted plates to separate and RF output reappeared. It took me quite a while to find the plate that was bent but once I found it and bent it straight the LOAD capacitor worked fine. You have to really look closely to find bent plates. I use a high intensity light shown through the plates while rotating the shaft and looking through the other side.

How about putting an ohm meter between the cap stator and ground. Then rotate the cap slowly and watch for a short.

Another problem can be arcing.

You need to know what you are looking for.

I agree Bob, an ohm meter can determine whether the fixed and variable plates are shorted.

I also agree, arcing can occur, especially of the load presented to the output of the PI Network is signficantly beyond the limited impedance matching range of the hybrid's PI Network.

My experience with arcing LOAD variable capacitors produces a sound that sounds like "sizzling" rather than a "pop" sound. The IP meter will also display an instantaneous change when arcing occurs.

The other problem is the wiper on the shaft of the capacitor. Connect an ohm meter between the shaft and ground and rotate the shaft. Rotate the shaft. It should always read 0 ohms.

Any variable capacitor that has been arcing is very difficult to repair.

> Compressed air cannot always clean away corrosion. Corrosion "tips" can occur on the plates due to the environment the component is subjected to. Since the radio has sat for a long time, corrosion tips can occur on the fixed and/or variable plates which compressed air can't remove. To remove corrosion you need to use a stiff piece of paper wet with contact cleaner and slide the paper between the plates. This doesn't always work either. It depends on how big the corrosion tips are. If you listen closely in a quite room, while rotating the LOAD control, a shorted variable capacitors will sounds like the fixed and variable plates are scrapping against themselves. You have to listen closely to hear it. I have run into LOAD variable capacitors where a variable plate, only one, was shorting to the fixed plate when the capacitor shaft was rotated only half way. When this happens, all RF is shorted to ground resulting in zero RF output. Rotating the LOAD control CCW a bit caused the shorted plates to separate and RF output reappeared. It took me quite a while to find the plate that was bent but once I found it and bent it straight the LOAD capacitor worked fine. You have to really look closely to find bent plates. I use a high intensity light shown through the plates while rotating the shaft and looking through the other side.

The vfo in my TS-520 is scratchy at the low and high end of its range. Is it necessary to remove the panel and VFO in order to to clean appropriate areas?

Thanks

joe k7mks

Check the side of the VFO housing. If it has the inspection panel, you can get to the spring contacts through it.

Hi people,when wanting to dip the plate i have to put the radio in the CW position on the mode switch as the meter does not register in the Tune position on the IP meter as it should,and i have done all of the tune up procedure correct up until this point yet can't understand why it is doing this??? :oS
Also the power on 80 meters into a 50 ohms dummy load with the plate idle current at 60ma when tuned for maximum output is 135 watts at 240ma on the IP meter,does this sound right?? As im sure my old TS-520S did 150+ when maxxed out.

It appears that resistor(s) R5 and/or R6, both 56K 1/2 watt, on the HV Unit board have strayed out of tolerance. Check both resistors and replace if found to be out of tolerance.

You say the IP meter shows 240ma with an RF output of 135 watts in CW mode. To correct the excessive IP current simply rotate the CAR control CCW until the IP meter shows 220ma. You either have the CAR control set too high or the LOAD control improperly adjusted. Are you tuning the 520SE into a dummy load or an antenna?

One other way to find shorts in a variable capacitor is to connect the variable capacitor in series with a 120 volt light bulb and look for sparks as you rotate the shaft. Of course be careful with the 120 volts.

I agree Bob, an ohm meter can determine whether the fixed and variable plates are shorted.

I also agree, arcing can occur, especially of the load presented to the output of the PI Network is signficantly beyond the limited impedance matching range of the hybrid's PI Network.

My experience with arcing LOAD variable capacitors produces a sound that sounds like "sizzling" rather than a "pop" sound. The IP meter will also display an instantaneous change when arcing occurs.

I forgot to mention about the 150+ watts output from your TS-520S.

The TS-520S is not designed to produce 150 watts output. If your watt meter is showing 150 watts output then the PI Network is not adjusted properly and you are putting undue stress on the final amplifier and the 520's power supplies. Any reactance in the antenna system can cause false increase in power output.

Shaun,

Yes, R5 and R6 can affect the flow of electrons in the final tubes which results in less IP current displayed on the IP meter in TUNE mode if the resistor values become significantly out of tolerance.

Resistors R5 and R6 on the HV Unit board form a resistive voltage divider network that reduces the final tube screen voltage in TUNE mode.

Here's an example. Lets say the voltage applied to the HV Unit "210" terminal is "210VDC". The voltage flows through R5 and R6 to ground. The TUNE terminal is connected at the junction of R5 and R6.

We must first determine the current through the series string of resistors R5 and R6. To do this we must use ohms law. Therefore, the total resistance of R5 and R6y is;

56000 + 56000 = 112000 ohms

To determine the current through the series string of R5 and R6 series resistors, we use the following formula

I = E / R

210 / 112000 = .001875

The same amount of current flows through "both" resistors.

We now can determine the voltage drop across R6, the first resistor in the string. To do that we use ohms law formula;

E = I x R

.001875 x 56000 = 105 volts (voltage drop across R6)

The voltage drop across R5 uses the same formula

.001875 x 56000 = 105 volts

To determine if our calculation are correct, we add the 2 voltage drops together and the answer "must" equal the source voltage of 210VDC. Are we correct in our calculations?

105 + 105 = 210

Yes we are because the 2 voltage drops added together equals the source voltage of 210VDC.

The voltage used in the above example are not the actual voltages, they are only examples. To determine what the actual voltage drops across R5 and R6 you would have to measure the actual voltage applied to the HV Unit's "210" terminal then use the formulas in the above examples to determine the current and voltage drops accordingly.

End of example.

Based on your comments about the IP current, switching to CW mode brought the IP current display on the meter back to normal, therefore allowing you to tune the 520SE up in CW mode but not in TUNE mode.

When the Mode switch is set to CW, USB, or LSB mode, the final tube screen voltage no longer flows through R5 and R6 on the HV Unit board but rather flows through R7, 12K 1/2 watt resistor, on the HV Unit board resulting in the screen voltage returning to normal.

I hope this answers any questions why R5 and R6 could be the source of your lack of IP current in TUNE mode. Try using the formulas and steps I outlined above to see how close you come to the actual voltage drop across resistors R5 and R6. As I said, you only have to measure the actual voltage at the HV Unit's "210" terminal then use the steps and formulas provided above to find out what the actual voltage at the "TUNE" terminal will be. Isn't electronics fun???

Hi Mike,wow that was some response :O),yes i have ordered some 56kohm resistors,let you know how i get on,again a BIG thankyou for your time & knowledge,cheers,Shaun :O)

>
> Yes we are because the 2 voltage drops added together equals the source voltage of 210VDC.
>
> The voltage used in the above example are not the actual voltages, they are only examples. To determine what the actual voltage drops across R5 and R6 you would have to measure the actual voltage applied to the HV Unit's "210" terminal then use the formulas in the above examples to determine the current and voltage drops accordingly.
>
> End of example.
>
>
> Based on your comments about the IP current, switching to CW mode brought the IP current display on the meter back to normal, therefore allowing you to tune the 520SE up in CW mode but not in TUNE mode.
>
> When the Mode switch is set to CW, USB, or LSB mode, the final tube screen voltage no longer flows through R5 and R6 on the HV Unit board but rather flows through R7, 12K 1/2 watt resistor, on the HV Unit board resulting in the screen voltage returning to normal.
>
> I hope this answers any questions why R5 and R6 could be the source of your lack of IP current in TUNE mode. Try using the formulas and steps I outlined above to see how close you come to the actual voltage drop across resistors R5 and R6. As I said, you only have to measure the actual voltage at the HV Unit's "210" terminal then use the steps and formulas provided above to find out what the actual voltage at the "TUNE" terminal will be. Isn't electronics fun???

I always tune up My TS520 in the CW mode.
240 Ma is a bit too hard on the tubes and HV power supply for me. You should back off on the load control until the plate tuning Ip dip is 200-220 mA !

The difference between 100 W and 135 W is not noticable on the other end of a QSO and much easier on the tubes.
 I have had the same tubes in the rig for 20 years now Running 100 W or less..

Hi, I'm with John. In looking in my insturction manual, it says to load the dip to 200 ma. in the CW position. If you work the math to come up with the difference in dB betweem 100 watts and 135 watts, you will discover that it will not make any difference at the receiving end. In addition, the life of your 6146's will be extended by not asking them to put our more power than they were designed to provide.
Hope this helps.....John K5IRK

Hi Guys,

I need to lower the output power to 10watts on my Ts520S for LIC requirements.

if I tune the set as per normal , then drop the drive back ,will I acheive this safetly with out harming the set???

I have the MODS DK circuit built , but am reluctant to use as it is not very convenient.

Jeff

Hello Steven,

Do you have the TS-530 service manual? If not you will need it to troubleshoot the problem.

Voltage levels on the AF Unit board are as follows:

TP-4 = 12VDC
TP-6 = 9VDC
Plug 11 pin 3 = 9VDC

If you do not have the TS-530 service manual, you can download it at Gordon's website

www.n6wk.com/kenwood/

Scroll down the page and click on the 530 service manual link.

The above voltages, and others, are listed on the 530 schematics in the 530 service manual.

Hi Jeff,

If you are referring to the CAR control set for lower power output in sideband (USB and LSB) then the answer is no. The CAR control has no control over RF output in sideband (USB and LSB) modes. The CAR control only controls RF output in CW and TUNE mode. You can't "preset" the CAR control during tune up for a lower power output in sideband. The MIC gain setting along with any ALC produced, controls the power output in sideband mode.

You can build a simple circuit using a 9VDC batter and a pot connected to the rear panel's 8 pin octal socket's external ALC connection to control RF output in sideband. I have never used this method on sideband.

Do not adjust the LOAD control only to reduce power output. Doing so will cause the transmitter's PI Network output impedance to be significantly different than the antenna impedance load presented to the transmitter.

I have a question.

You say the 530 has no receive and no transmit. I will assume that pressing the PTT microphone button and/or flipping the SEND switch places the 530 in transmit.

Does the digital display work? If not then the PLL Unit has become unlocked for what ever reason which will cause complete loss of both transmit and receive and the digital display will be dark, nothing showing except maybe the decimal points.

Hi Shaun...you will still get the same results on SSB by tuning your rig up to 200 ma and then switching to SSB compared to running it the way you have explained that you do...the extra watts won't make any difference on the receiving end by tuning it up in CW position to 135 watts out and then switching to SSB.... ..and your tubes will last a lot longer.....John

You can listen to your transmit audio by pressing the Monitor button. The Monitor push button is to the left and directly below the "FIX" push button on the front panel.

If you have stereo headphones, plug them into the front panel PHONEs socket while transmitting in sideband into a dummy load. Speak normally as you would if you were talking to a distant station. You can tell a lot about your transmit audio by simply listening to it using the TS-830S Monitor feature.

The Monitor push button is just "left" of the "VFO" and directly below the "FIX" push button. I left out the word "VFO" in my earlier response.

If your audio sound clean then the transmit signal will be clean.

Another way to monitor your transmit signal is to monitor the ALC meter. A good clean signal will be transmitted if the MIC gain is set so the ALC meter just starts to flicker, on voice peaks, above zero when speaking into the microphone at a normal voice level. If the ALC meter constantly rides up to the middle and top of the ALC scale then your MIC gain is set too high. There are a lot of stations that turn the MIC gain up too high so the meters flap up and down. If you listen closely at their audio you can hear the distortion.

30146. Help needed for an SM-220

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)

Hi Everyone,

I've just picked up an SM-220 off Ebay. It looks in good condition and powers up to give nice clean trace. I'm not familiar with the monitor at all but after going through the manual I've cabled it up and tried it on my 830. It seems to work ok apart from the int sync. The trace doesn't sync at all. I've just taken the covers off and there is a little rust on the inside of the bottom cover but cct boards and plugs and socket seem pretty clean. I'll clean it all up today including the sync switch. Does anyone know if there's a trigger adjustment anywhere?

The good news is.... I bought it advertised without the BS-8 fitted but when I opened it up. There it was! (I have to keep checking to see if it's just an empty BS-8 box. hi hi)

Update..........

It all seems to be working OK apart from monitoring transmission. The internal sync must be working as the BS-8 works. (It was a pain to set up though as the manual could be better). When monitoring transmission the display doesn't seem to be triggered at all and wanders all over the screen. Is this normal?

Yes, the relay does change from receive to send and the display is working. I hope to work on her a bit today and check the voltages. I have downloaded the service manual. Thanks for the info, I'll let you know what I come up with. 73 de AI4NV

Monitors of this type do not have triggered sweep. If you use the 2 tone input to your TX you can synchronize the sweep. But that's the best you can do.

It's possible to set some of these up to use the trapezoid pattern with out a linear amplifier. That is a more useful display for SSB.

Thanks Bob. It seems it's all working fine then. I've found that the two tone input works well for finding the optimum level and comp settings but watching the display during an actual ssb transmission doesn't seem to show a lot. It should be good for monitoring CW though. When using the compressor the displayed two tone waveform shows ripples around the peaks. Is this showing a problem? I've got good audio reports this afternoon so I don't think I've got much of a problem, if any. The SM-220 user manual and service manual leave a lot to be desired.

Yes watching the speech pattern while transmitting is difficult. If you set the vertical while in CW then you can watch the speech peaks in SSB.

I don't have a SM-220 but I do have 2 Heath monitors. The Heath monitors can be used with trapezoid mode by bringing out the speech amp from the transmitter. That's a much better way to monitor modulation.

I have no clue about the speech clipper.

I use the trap for SSB with or without the amp. I use the external input with a RF tank circuit pickup on the AM transmitter to watch % of modulation. Both modes work great.

please get back off line.
Have a beautiful complete TS-830 station for sale. The entire station is a easy 9/10 cosmetics.In 3 years have found no operating issues with any part of the station. Consists of the following:
1. TS-830s transceiver,ssb filter/no cw filter ,full output.box
2. VF0-230 all cables and manual,factory box.
3. SP-230 filtered speaker,manual,cable.
4. SM-220 station monitor scope, manual and all cables.
5. SHURE 522 desk mic.
6. kenwood MC-35s hand mic.
Would like to sell or trade the entire station as a complete package.
asking 1195.00 will split shipping: fedex insured
Trades considered flex SDR., late hf/6 rig,746 pro or ??: +/- $$$
If seperate sale: ts-830s-450.00,sp-230-130.00,vfo230-260.00,SM-220-275.00 shure mic-75.00,hand mic 35.00--split shipping on all.
pay pal +3% or usps MO.
thanks

No. Three cables with RCA connectors at each end are required for signals PLUS a 13.8 vdc power supply. The dc source may be taken from the connection on the back of a TS-520, but a proprietary connector is required at the DG-5 end.

Hi Mike,just to let you know you were 100% corect Mike,
R5 & R6 were shot at,one was reading something like 96 kohms & the other was not reading anything on my multimeter.
The new 56 kohm resistors arrived today so I installed them and my IP meter now works again in the Tune position,so yipee!!! :O)
Thanks so much for your help on this Mike,this group is a valuable asset & without it i may not of found the cure for my problem,so a great result.
Perhaps this info should be distributed online for other people with the same problem.
Regards,Shaun :O)

>
> Yes we are because the 2 voltage drops added together equals the source voltage of 210VDC.
>
> The voltage used in the above example are not the actual voltages, they are only examples. To determine what the actual voltage drops across R5 and R6 you would have to measure the actual voltage applied to the HV Unit's "210" terminal then use the formulas in the above examples to determine the current and voltage drops accordingly.
>
> End of example.
>
>
> Based on your comments about the IP current, switching to CW mode brought the IP current display on the meter back to normal, therefore allowing you to tune the 520SE up in CW mode but not in TUNE mode.
>
> When the Mode switch is set to CW, USB, or LSB mode, the final tube screen voltage no longer flows through R5 and R6 on the HV Unit board but rather flows through R7, 12K 1/2 watt resistor, on the HV Unit board resulting in the screen voltage returning to normal.
>
> I hope this answers any questions why R5 and R6 could be the source of your lack of IP current in TUNE mode. Try using the formulas and steps I outlined above to see how close you come to the actual voltage drop across resistors R5 and R6. As I said, you only have to measure the actual voltage at the HV Unit's "210" terminal then use the steps and formulas provided above to find out what the actual voltage at the "TUNE" terminal will be. Isn't electronics fun???

I first recommend cleaning all the plugs on the IF Unit board with contact cleaner. Use a cotton swab wet with cleaner and rub the swab on the pins then while the pins are still wet with cleaner insert the plug a few times. Follow the cleaning with generous use of canned air to remove any/all cleaner residue.

Clean one plug at a time.

Look at the RIT and XIT push buttons. Over time the buttons can collect "gunk" and "dirt" around the sides of the buttons and can prevent the buttons from sliding freely through the front panel. Clean the buttons with canned air. The RIT and XIT switches behind the push buttons are sealed so they can't be cleaned with contact cleaner.

Once completed, test for proper operation.

Perform all the cleaning with ALL power turned OFF and the primary power plug removed from the wall outlet.

Hi Shaun,

I'm glad to hear your 520 is back in full operation.

The response I gave you with all the resistor, math and voltages information was to show you why I felt R5 and/or R6 were the source of your problem.

If you want to see first hand what happens when a resistor changes value in a series circuit such as R5 and R6 on the HV Unit, you can build the same circuit but use a 9 volt battery as the source voltage.

Use the formulas I gave you. Once you build the simple series resistor network, do not measure the actual voltage at the junction of the 2 resistors but rather do the math (ohms law) calculations first. Once you have finished with your ohms law calculation then measure the voltage at the junction of the 2 resistor to see if your math is correct. Don't worry if you are off by half of a volt or if the voltage drops, added together, are something like 8.999VDC. That's fine. The key is to understand how the circuit works and what happens if something changes in the circuit and what to expect for a voltage reading.

Next, change one of the resistors to say 100K and repeat the process and you should see a "different" voltage at the junction of the 2 resistors which is exactly what happened in your 520, only your test jig with 9 volt batter is much safer and easier to mess around with.

This may seem trivial and possibility unnecessary but it is one of the foundations of understanding how current and voltages flow through series resistors and how if one resistor changes value how it affects the overall circuits connected to the resistor(s). It also teaches you about using simple ohms law math.

> >
> > When the Mode switch is set to CW, USB, or LSB mode, the final tube screen voltage no longer flows through R5 and R6 on the HV Unit board but rather flows through R7, 12K 1/2 watt resistor, on the HV Unit board resulting in the screen voltage returning to normal.
> >
> > I hope this answers any questions why R5 and R6 could be the source of your lack of IP current in TUNE mode. Try using the formulas and steps I outlined above to see how close you come to the actual voltage drop across resistors R5 and R6. As I said, you only have to measure the actual voltage at the HV Unit's "210" terminal then use the steps and formulas provided above to find out what the actual voltage at the "TUNE" terminal will be. Isn't electronics fun???

Will,
I am not sure the database on the group can help or not. I found the date of mine by taking the top cover off and looking at the IC date codes. There is a method of getting close to the date, but I did not keep the email or I can't find it. Check K4EAA's site also.

30162. TS-830S meter adjustment

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-03-12 15:13:52 UTC
From: WL
Topic: 30162 Message: 30162

Gentlemen,

I am a retired airline pilot fairly new to hamdom (18 months). A friend of mine bought a complete 830 rig and I am attempting to check it out for him. I corrected a dirty band switch problem but during tune-up I have to reduce the carrier to about the 9:00 position to the keep the meter at 225 ma which produces about 50 watts output. The thing I'm concerned with right now is that when the unit is initially powered up the meter goes to about 90ma then slowly (5 seconds) descends to and remains at 40ma. It seems that something is causing the meter to read incorrectly which affects everything including setting the bias. Can anyone give me an idea of what might be causing this and where I should start to correct the problem? Any help will be greatly appreciated.

30163. Re: 530, No transmit, no receive

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-03-12 16:08:39 UTC
From: wrench101
Topic: 30098 Message: 30163

Ok, I opened her up this morning and this is what I've found:

Rectifier board:

800 = 895
210B = 245
210A = 243
300B = 320
-C = -111
12 = -110
14A = 17.9

Final Sockets:

Pin 1 = 0
Pin 3 = 121
Pin 5 = -91

AF Unit:

12 = 11.5
TP4 = 9.8
TP6 = 9.0
Plug 11, Pin 5 = 3.2

Voltage at the top of the RF choke is at 895

The display is working properly, the relay clicks when switching from receive to transmit, no audio is present whatsoever. When the meter is in ALC mode and the unit is placed into transmit, the meter bounces slightly and returns home. Again, thanks to all for your input.

> >
> > Pin 1
> > Pin 3
> > Pin 5
> >
> > Last, measure the voltage at the top of RF choke "L2". RF Choke "L2" is inside the final amplifier's metal enclosure and is between the 2 final tubes. The top of RF Choke L2 connects to each of the final tube plates through the parasitic suppressors (each parasitic suppressor has a coil wrapped around a resistor and connected between RF Choke L2 and the top plate connector of each tube). The top cover of the final amplifier must be removed to make this measurement. RF Choke "L2" is the tall white cylinder with wire wrapped around it. Measure the voltage at the top of the RF Choke. The voltage at the top of RF Choke L2 should be the same as the voltage measured at the Rectifier Unit's "800" terminal.
> >
> > Use "extreme caution" when measuring these voltages. There are voltages inside the 530 that can kill you. All voltages are measure between the terminals indicated above and chassis ground. That measure the Red meter lead is connected to each terminal and the Black meter lead is connected to the 530's chassis.

> > >
> > > Hello all, been a while since I've been on. In the meantime, I've acquired a 530 on fleebay that's seen better days. I have no transmit and no receive. Rig powers up, meter lights up (now that I've changed the bulb!), no ALC, no IP, no RF, HV is around 450 to 500. Some idiot in the past decided to wrap the 6A fuse with aluminum foil when it blew which

you can imagine what the rig looks like. I've changed the HV caps, there are burn marks on the rectifier board which I've changed many diodes and resistors, the final board was burned, so I replaced the screen and cathode resistors, I performed the final cage repair that is noted on Ken's (k4eaa) website. So I've done some work, but my troubleshooting ability is poor. I noticed after working on the rectifier board that I lost some HV. I had about 900 before, but was worried about all the fried parts on the board. There was one bad diode, D10 if I remember correctly, and several resistors that were well out of tolerance. I'm not sure where to go next, any help would be greatly appreciated. 73 de AI4NV - Steve

Butch,

When the rig is off...does the meter return to the far left..or "0"? If it does..then a mechanical issue is not likely. Look in the operators or service manual, it tells how to adjust the "S" meter. When the rig is first turned the meters needle will go full scale and will fall back to "0" If it does not..adjustment is indicated.

Has anyone looked at the problem of the sm-220 drifting? From trawling the internet it seems that this is a common problem. Just wondered if anyone else had been there before I open it up (again!)

Having said that I'm really enjoying this monitor. I'm finding it really useful.

Date: 2011-03-13 10:45:54 UTC
From: John Hennessy
Topic: 30069 Message: 30170

ok, I've attempted the suggestions made here and unfortunately am not fixed yet. I opened the final cage area, discharged, removed the 6146B valve, cleaned sockets, wafer switches and all plates with deoxit followed by a blow out with compressed air. No cracks on the bandswitch coupler, it's as new with no signs of discoloring. Have not cleaned every connector as yet but can reveal the following behavior:

After adjusting the load control a little each time to arrive at 225ma I can get to that IP reading no problem but only have 50W of output power. If I wait up to 5 or more seconds while still in send the IP jumps to 350mA and the output power jumps at the same time to 100W. If I return to recv then straight back to send the problem remains. If I wait 4 or more seconds in between then I'm back to 225mA then a few seconds later it jumps back up to 350mA again. It's as if a component is breaking down full power.

Thanks for all the assistance so far. I'm sure its something simple but just haven't found it yet.

John.

Hi John,

A couple of things. Have you checked the TX/RCV relay contacts are clean. Also, loosen all of the pcb mount screws you can see, just half a turn and then tighten them up again. They ground various circuits to chassis and all sorts of weird and wonderful things can happen if one's getting a bad contact. Lastly, there's a solder joint right next to the finals valve caps. It gets mechanical stress every time the valves are removed. Resolder it in case it's dry. Just curious but what's the HT voltage level and what's it doing when the Ip varies?

John,

I will assume the 530 is connected to a dummy load with a watt meter.

Set the LOAD control fully CCW.

Set meter to ALC

Tune the DRIVE control for maximum ALC indication.

Switch meter to IP.

While watching the IP meter AND the watt meter, adjust the PLATE control for maximum reduction in IP meter indication.

Note the watt meter's indication. The peak watt meter indication should occur at the same point of maximum IP meter indication when adjusting the PLATE control.

Once maximum IP current reduction (IP dip) occurs, adjust the PLATE control CW or CCW, and note of the watt meter peak RF indication rises or falls. If the watt meter rises more than 10 to 15 watts then the final amplifier is not neutralized.

Before you place any component, make any adjustments, etc, perform the above test first.

John,

Another possibility is the relay on the IF Unit may be getting flaky. However, before focusing on the relay, lets make sure the final amplifier is not causing the problem, i.e., making sure the final amplifier is neutralized.

Butch,

Also, forgot to mention that you can cheat a bit on the "S" meter adjustment. If you do not have a signal generator, you can use the "calibrator signal." It will not be as accuate but, will give you and idea if the meter is working properly. Dial up frequency to about 14.175MHz with the "cal" signal "ON" adjust the drive control and vfo frequency for max "S" meter reading.The "cal" signal should be strong. You should see about S-8/9..you can adjust the pot as indicated. If the IF/RF boards are way out of alignment this adjustment will not be effective, and will only be fooling you even more. Check the basic alignment steps in the operator manual. Remember this is cheating...but will give you and idea..

Thanks for responding, Joe. Yes, when the radio is off the indicator returns to "0".

Butch,

When the rig is off...does the meter return to the far left..or "0"? If it does..then a mechanical issue is not likely. Look in the operators or service manual, it tells how to adjust the "S" meter. When the rig is first turned the meters needle will go full scale and will fall back to "0" If it does not..adjustment is indicated.

Subject: [TS-520_820_530_830] TS-830S meter adjustment

Gentlemen,

I am a retired airline pilot fairly new to hamdom (18 months). A friend of mine bought a complete 830 rig and I am attempting to check it out for him. I corrected a dirty band switch problem but during tune-up I have to reduce the carrier to about the 9:00 position to the keep the meter at 225 ma which produces about 50 watts output. The thing I'm concerned with right now is that when the unit is initially powered up the meter goes to about 90ma then slowly (5 seconds) descends to and remains at 40ma. It seems that something is causing the meter to read incorrectly which affects everything including setting the bias. Can anyone give me an idea of what might be causing this and where I should start to correct the problem? Any help will be greatly appreciated.

Mike and John:

Should the following statement:

"Note the watt meter's indication. The peak watt meter indication should
occur at the same point of maximum IP meter indication when adjusting the
PLATE control."

be changed to read *minimum* IP meter indication when adjusting the PLATE
control (maximum RF Out on
watt meter) ?

I've also found on the foil side of the IF board a few traces that have been purposely cut. Does anyone know if any traces should be cut at all? The cut traces are "near" L13 and also near connector 1. Thanks. 73 de Steve, AI4NV

> > >
> > > Last, measure the voltage at the top of RF choke "L2". RF Choke "L2" is inside the final amplifier's metal enclosure and is between the 2 final tubes. The top of RF Choke L2 connects to each of the final tube plates through the parasitic suppressors (each parasitic suppressor has a coil wrapped around a resistor and connected between RF Choke L2 and the top plate connector of each tube). The top cover of the final amplifier must be removed to make this measurement. RF Choke "L2" is the tall white cylinder with wire wrapped around it. Measure the voltage at the top of the RF Choke. The voltage at the top of RF Choke L2 should be the same as the voltage measured at the Rectifier Unit's "800" terminal.

Rig powers up, meter lights up (now that I've changed the bulb!), no ALC, no IP, no RF, HV is around 450 to 500. Some idiot in the past decided to wrap the 6A fuse with aluminum foil when it blew which you can imagine what the rig looks like. I've changed the HV caps, there are burn marks on the rectifier board which I've changed many diodes and resistors, the final board was burned, so I replaced the screen and cathode resistors, I performed the final cage repair that is noted on Ken's (k4eaa) website. So I've done some work, but my troubleshooting ability is poor. I noticed after working on the rectifier board that I lost some HV. I had about 900 before, but was worried about all the fried parts on the board. There was one bad diode, D10 if I remember correctly, and several resistors that were well out of tolerance. I'm not sure where to go next, any help would be greatly appreciated. 73 de AI4NV - Steve

Hi Joe,

Thanks for the help. I've had my 830 for over a year and have referred to both the owner's and service manual dozens, if not hundreds of times and apparently overlooked this every time. The meter is not an issue with my radio so maybe that's why I missed it. Anyway, the 14.175 marker was dead on and the meter adjustment was easy. S meter reads a solid S8 with the marker and zero with no signal. I noticed that on power-up the initial needle deflection is only to 50ma before it settles down to "0". There are other issues with my friends radio during tune-up and as a relative newby I'm working on a description that is both accurate and can be clearly understood. Bottom line is that after the tuning process I must reduce the carrier to about 9:00 to be at 225ma during key-up on CW showing about 50 watts out on the watt meter in my 949E. The carrier control is VERY sensitive. Moving the carrier from 9:00 to between 11:00and
12:00 results in movement from 225ma to full deflection. This radio is exceptionally clean both inside and out and I think is suffering mostly from non use. If anything I've described so far points in any particular direction please let me know. Again, thanks for the help with the meter adjustment. After reading your email it took about 9 seconds to find it in the owner's manual. Duh.

Butch,

Also, forgot to mention that you can cheat a bit on the "S" meter adjustment. If you do not have a signal generator, you can use the "calibrator signal." It will not be as accuate but, will give you and idea if the meter is working properly. Dial up frequency to about 14.175MHz with the "cal" signal "ON" adjust the drive control and vfo frequency for max "S" meter reading.The "cal" signal should be strong. You should see about S-8/9..you can adjust the pot as indicated. If the IF/RF boards are way out of alignment this adjustment will not be effective, and will only be fooling you even more. Check the basic alignment steps in the operator manual. Remember this is cheating...but will give you and idea..

Butch,

When the rig is off...does the meter return to the far left..or "0"? If it does..then a mechanical issue is not likely. Look in the operators or service manual, it tells how to adjust the "S" meter. When the rig is first turned the meters needle will go full scale and will fall back to "0" If it does not..adjustment is indicated.

Subject: [TS-520_820_530_830] TS-830S meter adjustment

Gentlemen,

I am a retired airline pilot fairly new to hamdom (18 months). A friend of mine bought a complete 830 rig and I am attempting to check it out for him. I corrected a dirty band switch problem but during tune-up I have to reduce the carrier to about the 9:00 position to the keep the meter at 225 ma which produces about 50 watts output. The thing I'm concerned with right now is that when the unit is initially powered up the meter goes to about 90ma then slowly (5 seconds) descends to and remains at 40ma. It seems that something is causing the meter to read incorrectly which affects everything including setting the bias. Can anyone give me an idea of what might be causing this and where I should start to correct the problem? Any help will be greatly appreciated.

Rick,

Does the "6" & "7" show up no matter what band? The 820S's are known for problems with frequency readouts. First..get yourself some DEOXIT..or similar. Turn OFF rig..and unplug. The DG-1 is on the left side of the VFO as you look at the rig, it has a multi-pin connector that goes to the frequency readout tube. Unplug that and use DEOXIT with a Q-tip on the pins..put connector back on and off several times. Blow off with "canned air." Do the same with the connector on the bottom of the DG-1 unit..you have to take off the bottom cover of the rig. Make sure all connectors are plugged back in. Plug back in...and check for operation. You MAY have to remove the DG-1 unit and remove the boards..one-by-one, and clean the pins/connectors on the inside, with procedure outlined above as above. If that does not work...then more is wrong. There are message threads here all about the problems with the 820S DG-1 diaplay.....good luck

Butch,

If the rig has been "mis-tuned," "over-driven," or taking an overly long time to tune up..over a period of possibly years..there are some components in the final cage area that can be damaged by excessive heat and or current. Also, check the value of the 4 (four) 20 ohm resistors on the final board. They should read about 5.0 ohms (plus/minus tolerance) to ground. Find an X-ray view of the final board...it does not have to be removed to check the resistors. The closer to 5 ohms the better. If these resistors are too far out of value, you will get and erroneous plate current reading/versus power out. Mike(w5rkl) may also add to this. Good luck.....

OK Folks my beloved TS-520 has a problem.

I have owned it brand spanking new since 1974.

As I was tuning up into a dummy load today.

My transmit RF gain control stopped having any effect in controlling the output..

The meter reads full scale on receive and shows like I am using full RF TX gain all the time in the tune position.

Any thoughts or ideas as to the cause before I delve into my beautiful TS-520.

Any help appreciated !!!!!!!):):

Jim

Hi Everybody,

I'm working on my 40 year old transmitter and I see quite a bit of dust in deep corners. I have seen references on this and some other lists about "canned compressed air". I don't do industrial work any more so I have no access to an air compressor. Where can I get "canned compressed air"?

I have to replace the "carrier" control on mine as the old one is intermittent. I disassembled it and the resistance material in the pot is worn through. I have only to wait for the new one to arrive. I put new finals in it about a year and half ago and now it also needs a new driver tube (40 years old!). I just happen to already have a couple of those and that transmitter is the reason I got them <g>. I can't find any 'measurable' output at the transverter terminal when I have that on (finals off). That is coupled from the driver tube.

I'm going to check/tweak the alignment too but that seems to be pretty close and is probably okay. It wants to work...just can't quite.

73,

Bill KU8H

Bill,

You can find "canned air" at Wal-Mart, and some other stores that have a computer section. I go to Costco (warehouse big box store) and buy in a 6 pack as I use it often. Your other problem...off the top of the head...I don't know.....several others in this group can probably help you.....

30190. TS-830s Final unit value R1

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-03-14 06:37:14 UTC
From: Chris Parnell
Topic: 30190 Message: 30190

Hi there,

Can anyone tell me what the value of R1 in the final unit board should be on the 830s please?
I cannot see it on the 830s Parts list☐ It lists R2 R5 then R7 and R8 only.

Thanks
Chris Parnell, ZL1CDP

Hello Chris,

R1 is 100 ohms.

Have a great day.

Chris,

R1 is shown on the 830 final unit schematic in the service manual. R1 is in series with L1 at the "FG" terminal that lead to pin 5 of the final tube socket pins 5.

30193. Transistors Q1, Q2, Q3, and Q7 on TS-820 AF-AVR Unit

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-03-14 15:49:08 UTC
From: ae5uu
Topic: 30193 Message: 30193

Does anyone have a source for transistors Q1, Q2, Q3, and Q7 found on the AF-AVR Unit of the TS-820? The original numbers are:

Q1 and Q2 2SC1000(GR)
Q3 TA7201P
Q7 2SA496Y

Thanks to a posting from W5RKL, I have located a new number and a source for Q4-6, NTE-85 (originally 2SC372.)

Again thanks to Mike, I now have a new part number and a source for D5, 1N5234B (originally WZ-061)

I found these parts at www.mouser.com

Hello Rick,

I assume you have a watt meter and more than likely it is an "average" power watt meter not a peak power watt meter.

When speaking in a normal voice level with the MIC gain set between 9 and 10 o'clock, the power output on any average power watt meter will be between 25 and 30 watts which is "normal".

If you set the meter switch to ALC and speak in a normal voice level into the microphone with the MIC gain set between 9 and 10 o'clock, the ALC meter should just start to flicker above zero. That's the point of maximum gain and peak power output even though your average watt meter only displays 20 to 30 watts.

Tune the 820 up in TUNE and CW mode for full output, approximately 100 to 110 watts. Switch to sideband and set the meter switch to ALC. While speaking in a normal voice level into the microphone, adjust the MIC gain so the ALC meter just starts to flicker above zero. This is the point of maximum gain and peak RF output even though your average watt meter only shows between 20 and 30 watts peak output.

Do not fall into the trap many others have by adjusting the MIC gain so the average watt meter shows upwards of 80 to 100 watts output. This will create loads of splatter, distortion in the audio at the distant receiving end, and over drive the final amplifier into non-linear operation.

There doesn't appear to be anything wrong with your TS-820.

Topic: 30199 Message: 30199

Thank you for your reply Gordon.

The exact Kenwood lettering for Q7 is 2SA496 (Y) on the AF-AVR (X49-1080-00) board. In the TS-820 Service Manual the part is listed as 2SA496. So I am at a loss as to which equivalent to pick, the NTE-374 (2SA496Y) or the NTE-185 (2SA496-Y).

If you have any further thoughts, I would enjoy hearing them.

For now I am going to hope that Q3 on this board is OK. But if anyone has a reference number for the TA7201P (11 input terminals), hovever, I would appreciate hearing about it.

Thanks. 73,

Russell

From: Jim S
Topic: 29281 Message: 30201

Perfectly normal! It all has to do with the ratio between a human voice's peak and average power. Average power of a voice is about 30 % of the peak. The meters on your 820 respond to AVERAGE power. Don't try to get any more out of the radio, or you will have distortion, clipping and all kinds of nasty stuff !

This question is asked about once a week on the QRZ forum !

30202. 530 No Transmit, No Receive

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-03-14 17:37:03 UTC
From: wrench101
Topic: 30202 Message: 30202

Well, I've done all I know to do. My 530 still won't receive or transmit. I have the following voltages:

Rectifier board:

800 = 895
210B = 245
210A = 243
300B = 320
-C = -111
12 = -110
14A = 17.9

Final Sockets:

Pin 1 = 0
Pin 3 = 243
Pin 5 = -91

AF Unit:

12 = 11.5
TP4 = 9.8
TP6 = 9.0
Plug 11, Pin 5 = 3.2

Voltage at the top of the RF choke is at 895

The display is working properly, the relay clicks when switching from receive to transmit, no audio is present whatsoever. When the meter is in ALC mode and the unit is placed into transmit, the meter bounces slightly and returns home. I am getting no idling current. I've cleaned connectors, replaced HV caps, cleaned bandswitch, cleaned pots, replaced screen and cathode resistors, took the cap off of RL1 and sprayed and worked the contacts, I've also found on the foil side of the IF board a few traces that have been purposely cut. Does anyone know if any traces should be cut at all? The cut traces are "near" L13 and also near connector 1. Seems like it should be something simple to me. The digital display follows the vfo when tuning. Previous owner sure messed things up a bit. On the rectifier board, R11 was jumpered, the 6A fuse was wrapped with foil. Most of the parts in the rectifier board have been replaced. I'm at a loss as what to do next. Again, all help is greatly appreciated. 73, Steve

First concentrate on fixing the receiver. You will probably find it is a common problem.

Do you know how to check the oscillators?

What kind of test equipment do you have?

From: w5rkl
Topic: 30202 Message: 30206

Put the 530 on 40 meters (7 on the band switch), push the Marker button to the right of the meter, and tune the VFO to a 25Khz dial interval, such as 7.025, 7.050, 7.075, etc. You should heat a beat note, a tone, and that beat note should vary in frequency up or down, depending on which direction you rotate the VFO at the 25Khz dial setting. When you hear the beat note, adjust the DRIVE control for a peak S meter reading. On 40 meters the S meter should display at least S9 or more when adjusting the DRIVE control for a peak S meter reading.

Do not key the transmitter when doing this test. This tests the receiver's front end and all stages up to and including the audio amplifier.

Do this same test on all bands. The S meter should peak at least S9 on all bands but 12 and 10 meters which is most likely will be S7 or slightly less.

Lets us know how this simple receive test goes. Again, do not key the transmitter, this is a receive test.

Topic: 30202 Message: 30210

Have you checked the rear panel SG slide switch to ensure it is in the "ON" Position? If the SG switch is not in the ON position and the Heater switch is not turned ON you will not see any USB and LSB idling current. Makes sure the SG switch is set to ON and the Heater switch is ON.

Since the display is displaying the ham band frequencies and changes, up and down, in frequency when you rotate the VFO, that tells me the VFO and PLL Unit are at least working. Having said that, just because those circuits are working doesn't mean the receiver will work.

Since you don't have any receive, no Marker (CAL) signal is heard at 25Khz intervals, that indicates a failure in the RF Unit board receive signal path either by a failure in transformer L41 (1.5Mhz) or receiver's RF amplifier Q1.

Please don't take this question the wrong way. What electronic troubleshooting and repair experience do you have? Attempting to troubleshoot and repair a 530 with very little, if any, electronic troubleshooting and repair experience is very difficult to say the least. Is there a ham club near you that you can ask for help from club members?

> transmit, no audio is present whatsoever. When the meter is in ALC mode and the
> unit is placed into transmit, the meter bounces slightly and returns home. I am getting no idling current. I've cleaned connectors, replaced HV caps, cleaned bandswitch, cleaned pots, replaced screen and cathode resistors, took the cap off of RL1 and sprayed and worked the contacts, I've also found on the foil side of the IF board a few traces that have been purposely cut. Does anyone know if any traces should be cut at all? The cut traces are "near" L13 and also near connector 1. Seems like it should be something simple to me. The digital display follows the vfo when tuning. Previous owner sure messed things up a bit. On the rectifier board, R11 was jumpered, the 6A fuse was wrapped with foil. Most of the parts in the rectifier board have been replaced. I'm at a loss as what to do next. Again, all help is greatly appreciated. 73, Steve

Chris,

R1 is shown on the 830 final unit schematic in the service manual. R1 is in
series with L1 at the "FG" terminal that lead to pin 5 of the final tube
socket pins 5.

50 W is TOO MUCH output for speech !!!
Watch the ALC meter, if you can advance the mic gain until the ALC meter is kicking up into the "normal" range on sylables, the mic audio is working ok !
 You should see peaks of around 25 watts on a wattmeter when you talk .
50 Watts is TOO MUCH output on SSB.
You can see 100 W ONLY on a peak holding wattmeter or calibrated oscilloscope !

Rick:

The normal way you check SSB power output versus mike gain is to inject a 1000 Hz signal into the mike input and see what that gives you on USB and LSB in terms of power output versus mike gain, then inject a 2500 HZ signal and see what it gives you and then inject a 350 Hz signal and see what you get.

You will get less power on the 350 HZ and 2500 Hz inputs than you will at 1000 hz for a given mike setting because of the passband of the SSB filter.

You can then adjust the carrier module USB and LSB frequencies to better match the passband of the SSB filter if you wish in order to make the signal balanced on each side. I did this a couple of times on my TS-820S after installing a new filter and finally decided that there was not enough difference to risk screwing up my careful alignment of the carrier freqs.

So, you can't just talk into the mike and see what it gives you.

Yes, SG is on. My circuit knowledge is somewhat limited, but I'm handy as a parts replacer. I've changed out the ones I could were visibly fried/bad. I was hoping that since I had no ALC, no bias current, no audio, that it would be one particular area that was preventing all from working properly. Thanks again. 73, Steve

30217. Re: [TS-520_820_530_830] Re: Tune up issues with old TS-530S

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-03-15 02:33:22 UTC
From: John Hennessy
Topic: 30069 Message: 30217

Yes, the 530 is connected to a dummy load via the AT-230 watt meter. I've even tried the dummy load direct on the back of the radio, same result. All is as you've noted below. My 50W output t 225ma starts to creep ever so slowly in time with the plate current rising then all of a sudden the jump to 100W with corresponds with 350ma of current. I quickly return to recv. I am aware that I should tune up quickly but during the process of testing of course identified that this runaway if I can call it that occurs within 6-8 seconds of transmit. I do no see the same problem in tune mode due to the lower power output I expect.

From your description and my symptoms it appears that I need to neutralize. I will get to this in a few days. While I'm here...Do radios normally ship neutralized from factory or is this a first required step for new owners?

Thanks Mike and group for the ongoing support.

John.

Hi Joe,

I tested the four 20 ohm resisters and got 13 ohms on all four. Possible? I tested several resisters with my trusty old Heathkit IT-28 which turned out to be very accurate. What do you think?

Butch,

If the rig has been "mis-tuned," "over-driven," or taking an overly long time to tune up..over a period of possibly years..there are some components in the final cage area that can be damaged by excessive heat and or current. Also, check the value of the 4 (four) 20 ohm resistors on the final board. They should read about 5.0 ohms (plus/minus tolerance) to ground. Find an X-ray view of the final board...it does not have to be removed to check the resistors. The closer to 5 ohms the better. If these resistors are too far out of value, you will get and erroneous plate current reading/versus power out. Mike(w5rkl) may also add to this. Good luck.....

Subject: Re: [TS-520_820_530_830] TS-830S meter adjustment

Hi Joe,

Thanks for the help. I've had my 830 for over a year and have referred to both the owner's and service manual dozens, if not hundreds of times and apparently overlooked this every time. The meter is not an issue with my radio so maybe that's why I missed it. Anyway, the 14.175 marker was dead on and the meter adjustment was easy. S meter reads a solid S8 with the marker and zero with no signal. I noticed that on power-up the initial needle deflection is only to 50ma before it settles down to "0". There are other issues with my friends radio during tune-up and as a relative newby I'm working on a description that is both accurate and can be clearly understood. Bottom line is

that after the tuning process I must reduce the carrier to about 9:00 to be at 225ma during key-up on CW showing about 50 watts out on the watt meter in my 949E. The carrier control is VERY sensitive. Moving the carrier from 9:00 to between 11:00and
12:00 results in movement from 225ma to full deflection. This radio is exceptionally clean both inside and out and I think is suffering mostly from non use. If anything I've described so far points in any particular direction please let me know. Again, thanks for the help with the meter adjustment. After reading your email it took about 9 seconds to find it in the owner's manual. Duh.
Best 73s,
Butch Lewis

Butch,

Also, forgot to mention that you can cheat a bit on the "S" meter adjustment. If you do not have a signal generator, you can use the "calibrator signal." It will not be as accuate but, will give you and idea if the meter is working properly. Dial up frequency to about 14.175MHz with the "cal" signal "ON" adjust the drive control and vfo frequency for max "S" meter reading.The "cal" signal should be strong. You should see about S-8/9..you can adjust the pot as indicated. If the IF/RF boards are way out of alignment this adjustment will not be effective, and will only be fooling you even more. Check the basic alignment steps in the operator manual. Remember this is cheating...but will give you and idea..

Thanks for responding, Joe. Yes, when the radio is off the indicator returns to "0".

Butch,

When the rig is off...does the meter return to the far left..or "0"? If it does..then a mechanical issue is not likely. Look in the operators or service manual, it tells how to adjust the "S" meter. When the rig is first turned the meters needle will go full scale and will fall back to "0" If it does not..adjustment is indicated.

Subject: [TS-520_820_530_830] TS-830S meter adjustment

Gentlemen,

I am a retired airline pilot fairly new to hamdom (18 months). A friend of mine bought a complete 830 rig and I am attempting to check it out for him. I corrected a dirty band switch problem but during tune-up I have to reduce the carrier to about the 9:00 position to the keep the meter at 225 ma which produces about 50 watts output. The thing I'm concerned with right now is that when the unit is initially powered up the meter goes to about 90ma then slowly (5 seconds) descends to and remains at 40ma. It seems that something is causing the meter to read incorrectly which affects everything including setting the bias. Can anyone give me an idea of what might be causing this and where I should start to correct the problem? Any help will be greatly appreciated.

This mosfet (3SK35) sits on a socket. It seems stuck. I want to put a NTE222 in its place and run the mosfet wide open. Anyone have any experience removing this transistor?
Regards,
Thomas

Hello Thomas,

All of mine pulled out quite easily. Are they all hard to move in the sockets? If you look down where the leads are inserted into the socket does it look like someone soldered the leads into the socket? The MOSFETs should come right out with very little effort.

The 4 original cathode resistors had a tolerance rating of 5% which means each cathode resistor, if out of tolerance by 5%, would have a resistance of "21 ohms" (20 + 5% = 21).

Butch, if the total cathode resistance is "13" ohms then one or more of the cathode resistors is out of tolerance. I agree with Joe and based on your total cathode resistance value of 13 ohms, replace all four of the 20 ohm 1/2 watt resistors. While you may find one or two of them close to 20 ohms, it's better to replace all 4 of them. Resistors are cheap and easy to find.

Mouser sells 1% metal film 20 ohm 1/2 watt resistors:

Mouser P/N:
71-CMF6020R000BHEB
Price:
45 cents each

They also sell Metal Oxide 20 ohm 1/2 watt 5% resistors:

Mouser P/N:
660-MOS1/2CT52R200J
Price:
8 cents each

Hooray! I found a cold solder joint on the IF board and now I have a marker signal! It's weak, but it's there. I completed the test you explained below and got close to S9 on all bands. I adjusted the coils per the owners manual for maximum meter deflection. So at least now I know she CAN hear. Now to find out why I have to output. The screen and cathode resistors have been replace. Until next time...73, Steve

Hi Steve,

That's great. Glad you found an open in the receive signal path.

The voltage readings you provide indicate there's no voltage problem.

You said the 530 has no idling current. This could be caused by relay RL1 on the IF Unit.

Relay RL1 on the IF Unit have 3 terminals that connect through the wiring harness to the AF Unit board. These 3 terminals control the AF Unit's driver and final tube biasing voltage levels between receive and transmit. What these 3 terminal do is turn ON and OFF 2 transistors on the AF unit. When the transistors are turned ON, the relay on the IF Unit is energized, the bias voltage level applied to the driver and both final tubes becomes "less negative", turning the driver and both final tubes ON. When the final tubes are turned ON, you see idling current in CW, USB, and LSB modes in transmit. When the relay on the IF Unit is not energized, receive mode, the AF Unit bias voltage level becomes "more negative" turning the driver tube and both final tubes OFF.

Now if the 3 RL1 relay terminals mentioned above are bad then the driver and both final tubes will remain "OFF" even in transmit and that's is why you do not see any idling current in CW, USB, and LSB modes. This, of course, is assuming the cathode resistors have not burnt open resulting in no current flow in the final tubes in transmit. Open cathode resistors will produce an "open" in the current flow path in the final tube which will result in no idling current in any mode.

The key is to watch the final tube voltages. In receive the voltages applied to the grid (negative voltage), the screen and plate (positive voltage) will be high in receive but become less in transmit when current is flowing in the tubes. If the voltages change only slightly, a few volts or so then I would look at RL1 on the IF Unit as a suspect, especially if the bias voltage doesn't change to a much less negative voltage on the grids of the final tubes.

If RL1 on the IF Unit is found to be bad, you can purchase an exact replacement through Ken, K4EAA, (www.k4eaa.com) or Mouser Electronics (www.mouser.com).

Mouser relay RL1 Part number:
769-NR4EB-12V

Mouser's Price:
$12.46 each

It's your choice who you purchase the relay from.

Steve,

I also recommend you checking the final tube cathode resistors as Joe suggested. The original cathode resistors are 5% carbon resistors and over time they can increase in value as I discussed in a recent response. As Joe said, you do not have to remove the 4 resistors. However, if the resistance of the cathode resistors is not 5 ohms or within 5% of 5 ohms I would replace all 4 cathode resistors, as I also mentioned.

I'm working on a 530 at the moment. I removed all 4 of the original cathode resistors. One measured "33 ohms". Now if you consider 5% tolerance rating of the original resistor then 33 ohms is "65%" above the original value. That 65% above the tolerance rating plus any additional increase above 5% tolerance with the other 3 resistors will result in a significant change in IP meter readings.

When the final tubes are conducting, a voltage drop occurs across the cathode resistors. This voltage at the final tube cathodes also appears across IP metering resistors R6 and R10. The voltage drop that occurs across R6 is applied to the meter switch IP terminal. When the 530 is in transmit and current is flowing through the final tubes, the voltage that appears at the junction of R6 and R10 is applied through the IP switch terminal to the meter in transmit and with the meter switch set to IP, you see the IP current displayed on the top scale of the meter. If no current is flowing in the final tubes, for what ever reason, there will be no voltage drop occurring across the cathode resistors and no voltage appearing across R6 and R10 which results in no IP meter indication in transmit.

I hope this helps you understanding how the IP meter works and what has to happen in order for the IP meter to display IP current in transmit.

Even though Mouser's page for these resistors says 5% tolerance, it
really means + or - 5%. Generally, resistors are specified with a +/- %
tolerance. So a 20 ohm resistor with a +/- tolerance of 5% still could be
at the limit of in spec at either 21 ohms or 19 ohms. If resistance in
spec tolerance is highly important in the design, the +/- 1% resistors
are what should be used.

Thanks! You just answered the question I had in mind regarding which one to buy.
Thanks again

Even though Mouser's page for these resistors says 5% tolerance, it
really means + or - 5%. Generally, resistors are specified with a +/- %
tolerance. So a 20 ohm resistor with a +/- tolerance of 5% still could be
at the limit of in spec at either 21 ohms or 19 ohms. If resistance in
spec tolerance is highly important in the design, the +/- 1% resistors
are what should be used.

Topic: 30162 Message: 30228

This circuit is not NASA Rocket Science where exact values within 1% must be adhered to. The radio will perform equally well with new 5% resistors just as it will with new 1% resistors. My response simply gave you 2 options to choose from. Whether you select 1% or 5% tolerance resistors is entirely up to you.

Butch & Mike,

Mike, thanks for answering Butch....I've been under the WX the past few.
Butch, stick with Mike's recommendation. Use the specified values...especially
the wattage! Good luck.....

73's joe wb7uqu

Subject: [TS-520_820_530_830] Re: TS-830S meter adjustment

This circuit is not NASA Rocket Science where exact values within 1% must be
adhered to. The radio will perform equally well with new 5% resistors just as it
will with new 1% resistors. My response simply gave you 2 options to choose
from. Whether you select 1% or 5% tolerance resistors is entirely up to you.

30230. TS-520 HELP

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-03-15 21:09:38 UTC
From: jsloss
Topic: 30230 Message: 30230

My -520 has an Ip and PO "glitch". When in LSB or USB and switching to SEND there is a momentary Ip increase to 100-150 ma with appropriate power out. Does it with RCA or GE finals. Replacing Driver tube does not seem to increase or decrease problem.

Neutralization is set correctly and I'm beginning to think the carrier null is not. Renulling carrier in LSB improves thje situation but does not help USB. For some reason cannot get a good null on USB and LSB at same control setting.

Any trhoughts?

JKoe k7mks

No mic inserted and VOX is off. Momentary spike drops back to normal in under a second or two.

I agree with Gordon.

The driver tube, on it's own, does not produce any RF signal. The driver tube simply amplifies the RF signal given to it by the transmit mixer.

You may not achieve an exact carrier null that matches both USB and LSB. This is assuming the other adjustments are right. TC1 and VR2 work together to achieve the lowest possible carrier null between USB and LSB. Quite often you have to accept a compromise so both USB and LSB have a very low carrier null. I use a separate receiver tuned to the frequency of the transmitter and adjust the pot and variable capacitor for the lowest S meter reading possible between USB and LSB.

Mike:

I can get a good carrier null in LSB when listening to an adjacent radio. PA Ip is 60 ma. When I switch back to RCVE and then back to SEN D Ip spikes to150-200 ma w/ corresponding PO. This spike drops back to 60 ma Ip in less than a second. The end result would be throwing a 20-30 watt carrier on your frequency, for just a second or less, whenever you keyed mike to transmit.

The same situation will occur in USB if I sought maximum null of the carrier in that mode.

Something is causing something to increase the Ip, even only momentarily, when switching from RCVR to SEND.

Thanks for your comments.

The relays seem to be switching fine as tested through plugs 8 and 9 on the AF board. The cathode resistors were replaced a week or so ago and are reading 5.7 ohms "in circuit" which I assume is fine. Question, the state of the tubes are unknown, with all the very bad things that I've seen performed from a previous owner, could the tubes be fried? It is apparent to me that a previous owner was a complete numbscull. I wasn't sure if I'd said so previously, but the rectifier board was fried because a jumpered R11 and a foil wrapped fuse. Screen and cathode resistors were fried completely and have been replaced. I also completed a partial final cage repair purchased from Ken. (all my parts have come from Ken minus a few resistors and diodes). I recently found a bad solder joint on the rectifier board (silly me) and corrected my HV meter reading. All voltages seem to be correct. I'm wondering if replacing tubes is my next step, Everything else seems to be functioning now, but no bias, no idle current, no ALC. Suggestions? Thanks to all. 73 Steve

>
> Steve,
>
> I also recommend you checking the final tube cathode resistors as Joe suggested. The original cathode resistors are 5% carbon resistors and over time they can increase in value as I discussed in a recent response. As Joe said, you do not have to remove the 4 resistors. However, if the resistance of the cathode resistors is not 5 ohms or within 5% of 5 ohms I would replace all 4 cathode resistors, as I also mentioned.
>
> I'm working on a 530 at the moment. I removed all 4 of the original cathode resistors. One measured "33 ohms". Now if you consider 5% tolerance rating of the original resistor then 33 ohms is "65%" above the original value. That 65% above the tolerance rating plus any additional increase above 5% tolerance with the other 3 resistors will result in a significant change in IP meter readings.
>
> When the final tubes are conducting, a voltage drop occurs across the cathode resistors. This voltage at the final tube cathodes also appears across IP metering resistors R6 and R10. The voltage drop that occurs across R6 is applied to the meter switch IP terminal. When the 530 is in transmit and current is flowing through the final tubes, the voltage that appears at the junction of R6 and R10 is applied through the IP switch terminal to the meter in transmit and with the meter switch set to IP, you see the IP current displayed on the top scale of the meter. If no current is flowing in the final tubes, for what ever reason, there will be no voltage drop occurring across the cathode resistors and no voltage appearing across R6 and R10 which results in no IP meter indication in transmit.

> >
> > You said the 530 has no idling current. This could be caused by relay RL1 on the IF Unit.
> >
> > Relay RL1 on the IF Unit have 3 terminals that connect through the wiring harness to the AF Unit board. These 3 terminals control the AF Unit's driver and final tube biasing voltage levels between receive and transmit. What these 3 terminal do is turn ON and OFF 2 transistors on the AF unit. When the transistors are turned ON, the relay on the IF Unit is energized, the bias voltage level applied to the driver and both final tubes becomes "less negative", turning the driver and both final tubes ON. When the final tubes are turned ON, you see idling current in CW, USB, and LSB modes in transmit. When the relay on the IF Unit is not energized, receive mode, the AF Unit bias voltage level becomes "more negative" turning the driver tube and both final tubes OFF.
> >
> > Now if the 3 RL1 relay terminals mentioned above are bad then the driver and both final tubes will remain "OFF" even in transmit and that's is why you do not see any idling current in CW, USB, and LSB modes. This, of course, is assuming the cathode resistors have not burnt open resulting in no current flow in the final tubes in transmit. Open cathode resistors will produce an "open" in the current flow path in the final tube which will result in no idling current in any mode.
> >
> > The key is to watch the final tube voltages. In receive the voltages applied to the grid (negative voltage), the screen and plate (positive voltage) will be high in receive but become less in transmit when current is flowing in the tubes. If the voltages change only slightly, a few volts or so then I would look at RL1 on the IF Unit as a suspect, especially if the bias voltage doesn't change to a much less negative voltage on the grids of the final tubes.

When you hear the beat note, adjust the DRIVE control for a peak S meter reading. On 40 meters the S meter should display at least S9 or more when adjusting the DRIVE control for a peak S meter reading.

You said "no bias". Did you check the bias supply to determine there's no bias? If there is no bias voltage then the final tubes, along with the driver tube, would conduct at saturation levels in receive which would most likely lead to the fuse blowing.

I can't say whether the tubes are good or bad. You would have to take voltage measures of the final tube grid, screen, and plate voltages during receive and transmit. The 530 service manual schematic shows typical final tube grid, screen, and plate voltage levels in both receive and transmit. The voltages shown in brackets are with the 530 in transmit. The voltages shown not in brackets are with the 530 in receive. The voltage measurements will tell a lot about how the final tubes are conducting and how the final amplifier is working. This also applies to the driver tube as well.

You said the relays seem to be switching fine as tested through plugs 8 and 9 on the AF Unit. That's fine but that's only half of the switching action. You have to go further to ensure the bias voltages are actually switching.

The actual driver tube bias voltage appears on AF Unit plug 7 pin 5 "DRB" (DRiver Bias).

The actual final tube bias voltage appears on AF Unit "FG" (Final Grid) terminal.

In receive, the DRiver Bias voltage (DRB) is approximately -51VDC. Switching to transmit the DRiver Bias voltage (DRB) changes to approximately +.4VDC. The voltage changes are measured/monitored on AF Unit plug 7 pin 5.

In receive, the Final Grid bias voltage (FG) is approximately -110VDC. This high negative voltage applied to the Final Grids turns both final tubes OFF (biased to cut off). Switching to transmit, the Final Grid voltage (FG) changes to approximately -65VDC. This "less negative" bias voltage when applied to the final tube grids, turns both final tubes ON and is measured/monitored on the AF Unit "FG" terminal.

These two bias voltage measurements/monitoring will only tell you whether the IF Unit relay and all bias switching circuits are working and the bias voltage is actually present at plug 7 pin 5 and FG terminals on the AF Unit. The bias voltage flows to the driver and both final tubes and should appear at pin 2 of the driver tube and pin 5 of both final tubes. This will check the entire bias switching circuit and bias voltage path to the driver and both final tubes. I say this since you said a previous owner messed up the 530 before you got it. Never assume anything, check it to be sure.

I mean no disrespect, I just think it's important to check everything to be sure especially since you said the condition of this 530 is bad because of a previous owner messing thing up.

Steve,
Thank you. I will check on the soldering and then get someone to hold the socket while I see if the transistor will come out.

The bias voltages at the said locations seem fine, although nothing shows at the meter. I've checked the meter circuits and they also appear to be fine. Everything is switching voltage at the tube contacts. Looking at the final tubes themselves, they don't appear to be as clean as others I've seen.

This "less negative" bias voltage when applied to the final tube grids, turns both final tubes ON and is measured/monitored on the AF Unit "FG" terminal.
>
> These two bias voltage measurements/monitoring will only tell you whether the IF Unit relay and all bias switching circuits are working and the bias voltage is actually present at plug 7 pin 5 and FG terminals on the AF Unit. The bias voltage flows to the driver and both final tubes and should appear at pin 2 of the driver tube and pin 5 of both final tubes. This will check the entire bias switching circuit and bias voltage path to the driver and both final tubes. I say this since you said a previous owner messed up the 530 before you got it. Never assume anything, check it to be sure.
>

> I mean no disrespect, I just think it's important to check everything to be sure especially since you said the condition of this 530 is bad because of a previous owner messing thing up.

> > The relays seem to be switching fine as tested through plugs 8 and 9 on the AF board. The cathode resistors were replaced a week or so ago and are reading 5.7 ohms "in circuit" which I assume is fine. Question, the state of the tubes are unknown, with all the very bad things that I've seen performed from a previous owner, could the tubes be fried? It is apparent to me that a previous owner was a complete numbscull. I wasn't sure if I'd said so previously, but the rectifier board was fried because a jumpered R11 and a foil wrapped fuse. Screen and cathode resistors were fried completely and have been replaced. I also completed a partial final cage repair purchased from Ken. (all my parts have come from Ken minus a few resistors and diodes). I recently found a bad solder joint on the rectifier board (silly me) and corrected my HV meter reading. All voltages seem to be correct. I'm wondering if replacing tubes is my next step, Everything else seems to be functioning now, but no bias, no idle current, no ALC. Suggestions? Thanks to all. 73 Steve

I see you said the SG switch is set to ON but you might check the voltage at the "SG" terminal on bottom of the final amplifier PC board. The SG switch could be bad. If the voltage on the "SG" terminal on the bottom of the Final Unit is "negative", even if the SG switch is set to ON, then the final tubes will not conduct and you will not see any IP idling current in transmit.

You said the voltages at the said locations seems fine. What is the actual voltages at the Final Unit's "FG" terminal in receive and transmit?

SG voltage at the SG terminal on the final unit, as well at pins 3 on both final tubes, is at 242. The FG terminal, as well as pins 5 on both final tubes, is at -101 in receive, and -71 in transmit.

Thanks again, 73, Steve

Hi Steve,

If the "SG" terminal voltage is 242VDC in receive, what is the screen voltage in transmit?

The "SG" final tube screen voltage should be less in transmit then in receive if the final tubes are conducting. The "SG" screen voltage reduction in transmit will vary depending on the level of conduction in the final tubes but it should not be the same in transmit as it is in receive.

The SG voltage does not change when transmitting, which would tell me that the finals aren't conducting, correct? I get 121 volts on SG while in "tune" mode, which I assume is correct. It also does not change when transmitting. It seems that the bias voltage is changing in an attempt to turn the tubes on, but nothing is actually happening. Are these fried? Would this be the reason that I also have no ALC reading on the meter?

If the final tube screen voltage is the same whether the 530 is in receive or transmit, even though the grid voltage changes from -101VDC to -71VDC in transmit, if no electrons are emitting from the indirectly heated cathode then there will zero ALC (grid current) and zero IP current.

I would replace the final tubes. You can get replacement 6146B tubes from the following source:

http://www.vacuumtubes.net/

It appears to me, based on the screen voltages between receive and transmit, whether in TUNE or CW/USB/LSB, that neither of the final tubes are conducting which is why there is zero ALC and zero IP current indications on the meter.

Hi Joe,

RL1 on the GENERATOR BOARD, when energize in transmit, provides a path for the CAR UNIT RF signal to the balance modulator. In receive RL1 is not energized which removes the CAR UNIT signal from the Balance Modulator.

Guys, pre suppose I wanted to do some QRP operating utilising my 830s;
My questions would be: is it better to tune and load the rig, as normal, and then reduce the output power by screwing back the output power by use of the carrier control switch or, tune and load the rig to full output power and, using the ALC minus voltage feature (minus alc via the skt on the back of the rig) reduce power that way. I know the rig is not designed for this type of operating at large, but I am trying to understand if it will shorten bottle life or have any impact at all on the final output stage running QRP for a period of time. The ultimate answer is run an 817 or similar but you work with what you've got !!

Kind regards.....Will

Hello Will,

Are trying to run QRP on CW or sideband? If it's sideband the CAR control has no control over power output in sideband.

For sideband, tune the 830 up for maximum power then control RF output through the external ALC connection.

My TS520 has a filament on/off switch to save battery current when mobile and no transmitting is planned.
If the 530 has a similar switch, make sure it is on or the filaments on the tubes light up before replacing anything. !
Forgive me if you already verified lit up filaments ...:D

I have operated my TS520 by setting the loading capacitor to minimum, re dipping the plate capacitor (usually somewhat reduced power output now) finally using the carrier setting to reduce further to desired power output. I have gotten down to 3/4 watts (750 mW) this way and have worked some good distances with a clean note .

This only works for CW mode !

Subject: Re: [TS-520_820_530_830] TS830S _ QRP ops

I have operated my TS520 by setting the loading capacitor to minimum, re dipping the plate capacitor (usually somewhat reduced power output now) finally using the carrier setting to reduce further to desired power output. I have gotten down to 3/4 watts (750 mW) this way and have worked some good distances with a clean note .

This only works for CW mode !

Subject: [TS-520_820_530_830] TS830S _ QRP ops

Guys, pre suppose I wanted to do some QRP operating utilising my 830s;
My questions would be: is it better to tune and load the rig, as normal, and then reduce the output power by screwing back the output power by use of the carrier control switch or, tune and load the rig to full output power and, using the ALC minus voltage feature (minus alc via the skt on the back of the rig) reduce power that way. I know the rig is not designed for this type of operating at large, but I am trying to understand if it will shorten bottle life or have any impact at all on the final output stage running QRP for a period of time.
The ultimate answer is run an 817 or similar but you work with what you've got !!

Kind regards.....Will

The filaments are working. With the help and great advice from the folks in this group, it has been determined that the finals in the rig are shot. A previous owner had done some pretty bad things to this rig. I should have new tubes by Friday and I can't wait to finally get on air. Thanks for the input though. 73 Steve

I don't understand why you would want to do this. While the NTE 222 is better than a 3SK 40 but only in the front end, the 3SK 35 is every bit as good as the NTE 222.

Also, why would you want to run the front end wide open ? All you are going to get is more noise and intermod.

The 3SK35 is a mosfet.

More sensitivity does not mean hearing more. The problem is signal to noise ratio. The noise floor on all HF bands is high enough that a further increase in gain will not improve things. Once a signal is in the ambient noise, you are not going to pull it out. This is true for AM and SSB which is a form of AM.

Now FM is a different story.

This mosfet (3SK35) sits on a socket. It seems stuck. I want to put a NTE222 in its place and run the mosfet wide open. Anyone have any experience removing this transistor?

Hi Mike,
sorry, I should have made it clear that I am only using CW. Yes, I appreciate that the mic and carrier controls are of no use when using SSB voice but its purley CW. I had just wondered if in doing so, it might do some form of harm to the output bottles, ie, generated heated etc as, in reality, the rig is designed to run much greater power levels than 3 to 5 watts.
regards

Will

Bob,
using the MIC control will not do anything other than upset the ALC of the rig and will, in effect, cease to function. I guess that it would reduce the transmitted audio down to whispers but it would not reduce the actual emitted rf to the low level I want. In any case, I am actually only wanting to work QRP CW so the carrier control should work. I am more concerned to learn if, in doing so, reducing the carrier to around 3 - 5 watts, it will impact on the final tubes ? heat etc ??

kind regards

Will

Will,

I believe you are wrong about the MIC control on SSB. On all other SSB rigs this is how you set the power level. From what I have been able to read the these rigs are the same.

Running CW at a 5W power level will not hurt the final at all.

Hi Will,

The rig gets a much easier life on low power. When I use my 830 for bpsk31, I tune up to full power and then use the mic gain to limit the rf power out. I use the plate current to set it up. At an Ip of around 100 mA it puts out around 20 watts RF and the signal couldn't be better. I get IMD reports of -28db. If I look at the ALC when transmitting it doesn't even leave the bottom peg. It's the same for CW. When you're set up for CW, tune for full power and then reduce the CAR as you watch the plate current and you'll see it go down. The less current that goes through the tubes, the less heat they'll generate. The tubes are also happier if the finals are in resonance that's why it's important to tune up as normal first.

Hello Will,

The MIC gain controls the level of audio applied to the balance modulator in sideband (USB and LSB).

In sideband, the audio from the speech amplifier is what varies the 8Mhz carrier signal level fed to the IF Unit. The lower the MIC gain setting the lower the audio level from the speech amplifier is applied to the balance modulator. This results in a lower level of 8Mhz carrier RF signal being applied to the IF Unit which ultimately results in lower RF output from the 830.

There is no requirement to "always" have ALC indication when transmitting in sideband whether USB or LSB.

ALC is produced when the level of RF signal from the driver tube to the final grids causes the final tube grids to swing positive during a portion of the RF sine wave cycle.

The final amplifier's in all of the hybrids operate in Class AB1. Normal Class AB1 amplifiers do not have grid current flowing during any portion of the RF or AF sine wave. The only time ALC is needed is when the level of RF signal from the driver tube causes the final tube grids to swing positive during a portion of the RF sine wave driving signal. Other than that, there's no need or requirement for ALC to be produced at any lower power setting and lack of ALC at lower power setting will not result in any negative affects or damage to the transmitter and transmit signal.

If QRP CW is desired, simply tune the transceiver up for maximum power output following the normal tune up procedures. Then once that is completed, switch to CW, key the transmitter and rotate the CAR control to the desired RF output level.

As for whether this will harm the transceiver? The answer is absolutely not.

73s
Mike

Topic: 30266 Message: 30266

Does anyone know the exact inductance of the Plate choke L2 for the TS-830S?
I could remove one from an 830 to measure, but wondered if someone knows off hand. I know it is 206 turns of #34 enameled wire

Thanks,
Gordon

I guess that it would reduce the transmitted audio down to whispers but it would not reduce the actual emitted rf to the low level I want. In any case, I am actually only wanting to work QRP CW so the carrier control should work. I am more concerned to learn if, in doing so, reducing the carrier to around 3 - 5 watts, it will impact on the final tubes ? heat etc ??

Thanks Mike, but that is the wrong one. That is the one mounted on the Finals board. I need the stand up Ceramic Plate Choke value that has the suppressors attached to the top.
I think it is around 170uh

Yep, wrong one. The part number for the Final RF Choke is L33-0635-05 but there's no value listed in the service manual's part list under "General" parts. I tried to find it using search engine but nothing that says what the inductance is.

I took one out of another radio and measured it it shows 162uh on my
digital meter that seems to be very accurate. So the factory value is
probably 160uh
I just rewound the burnt one but added too many coils so it shows 170uh.
Time to remove a few turns :-)

Thanks,
Gordon

Gordon--I kind of miss the days of lattice or pi-wound plate chokes like National made. The old Heath, Collins, Johnson rigs used them. I guess they were too difficult to wind and too expensive so they went to the solenoid wound chokes. I have not seen what the early Kenwood hybrids used. I wonder if these solenoid chokes are burning up due to too high of plate current or due to self-resonance?? The ones in my Kenwood TS-530SP and TS-830Ss are not discolored, but I have never swept them (grid dipped) to see if they have any self-resonance in the ham bands. I was also surprised to see that they used #34 gage wire. Seems like I remember making some chokes years ago and I thought I used #24 or #26 wire? You clearly have far more experience than I do. Just curious whats going on here and if I need to be concerned about my rigs. Maybe I should contact Bob Mansker and buy a spare? Terry K9TW

Topic: 30266 Message: 30277

Hi Terry,

If I remember correctly the TS-820 had one of the older looking PI-wound/lattice milti coil type RF Chokes you are talking about. The part list doesn't list the inductance value (P/N L33-0217-15).

I would think if the choke windings are nice and shinny then you don't have anything to worry about. IF the choke windings are discolored, turn dark, then you should be concerned.

73s
Mike

Topic: 30266 Message: 30278

I'll jump in here with my own personal opinion. I doubt that Kenwood would have used an improperly designed choke in their rigs. If that had been the case, there would have been hundreds of rigs going back for replacement of the part early on. That apparently did not happen.

So many of these rigs have gotten into the hands of freebanders, and other users that really had no idea of how to tune a rig properly. "All knobs full right" was their attitude, and if they could get another 10 or 20 or more MA out of their tubes, they would do it! That, more than anything else, is probably the cause of more burned up cathode resistors and plate chokes than anything else.

If your radio has burned resistors, and/or chokes, and has difficulty performing well on 10, but works great on 11, THAT is an almost sure bet that it was the victim of "The golden screwdriver" !

As I say, this is just my humble opinion.

73 and good luck with that rig. Jim AG3Y

Gordon--I kind of miss the days of lattice or pi-wound plate chokes like National made. The old Heath, Collins, Johnson rigs used them. I guess they were too difficult to wind and too expensive so they went to the solenoid wound chokes. I have not seen what the early Kenwood hybrids used. I wonder if these solenoid chokes are burning up due to too high of plate current or due to self-resonance?? The ones in my Kenwood TS-530SP and TS-830Ss are not discolored, but I have never swept them (grid dipped) to see if they have any self-resonance in the ham bands. I was also surprised to see that they used #34 gage wire. Seems like I remember making some chokes years ago and I thought I used #24 or #26 wire? You clearly have far more experience than I do. Just curious whats going on here and if I need to be concerned about my rigs. Maybe I should contact Bob Mansker and buy a spare? Terry K9TW

The single layer chokes can be rewound. Discoloring is not a problem unless there are shorted turns.

Hi Terry,
This choke, and everyone I have ever seen burnt up, was due to abuse or bad finals.
The gauge is definitely 34 . I have every size enameled wire here from 22 up to 34.
I measured it with a micrometer before I started winding so I knew had had the correct gauge.

73,
Gordon
N6WK

Mike: Very interesting that the TS-820 had the pi-wound choke and later models went to the solenoid wound ones. I dont know the history of my rigs but the plate choke windings are different colors. One is kind of a brass color and the other has more of a reddish tint. Neither one is black over entire length and neither one appears to have any hot or melted spots on them. I guess I was wondering if Kenwood hybrid plate chokes had a history of problems with series resonance (maybe with addition of the warc bands?) which can be far more of a problem than the precise inductance value. I see on Ken K4EEA website pictures of failed choke that appears discolored (burned black) over entire length of winding. I have no operational issues with my rigs so far, just was interested in what the failure mechanism was that caused Gordon to have to wind a new plate choke. From your response it appears not a common problem with Kenwood hybrid design that I have to be concerned with. Sounds like it may be from operator error from too high plate current. Thanks for feedback. 73s Terry

Hi Terry,

If I remember correctly the TS-820 had one of the older looking PI-wound/lattice milti coil type RF Chokes you are talking about. The part list doesn't list the inductance value (P/N L33-0217-15).

I would think if the choke windings are nice and shinny then you don't have anything to worry about. IF the choke windings are discolored, turn dark, then you should be concerned.

73s
Mike
W5RKL

Gordon--Wasnt doubting you. I knew you had to have miked the wire. I looked at both of my chokes where the lead terminates at the top of the form with the parasitic suppressors and it sure looks like a very small gauge wire. I havent looked at wire tables, but I bet the ampacity of 34 gauge magnet wire in free air isnt 2 or 3 times our normal plate current? I am not design engineer so not sure what would be normal reserve. I would think you would want something around 400 to 500ma? Maybe the air movement of the cooling fan helps dissipate the heat from the choke. I appreciate knowing that the failures you are seeing are from shorted finals and/or operator error and not series resonance. I mentioned to Mike that my two chokes are different colors but that may be normal between a TS-530 and TS-830 and differing production runs. I dont want to make problem that doesnt exist but I want to keep my boatanchor treasures going for as long as I will last! With parts getting harder and harder to get it is good to know that I could look to you to wind a replacement. Thanks for feedback. 73s Terry

Topic: 30266 Message: 30283

I don't believe one or two instances of high current during tuning would cause the choke wiring to overheat to the point of shorting failures. More then likely failures in the RF choke, overheating to the point the insulating varnish on the wire melts and the windings short is caused by continuous abuse by operators. The same applies to the cathode resistors. I have seen cathode resistors that were completely destroyed, bodies burnt, cracked, and that doesn't come from a few short durations of excessive current flowing through them. Destroyed resistors and RF chokes are caused by consistent abuse, day in and day out, not because of a short duration of high current flowing through them.

Hi Will,

I'm jumping in here with own personal experience that will reinforce the excellent advice others have given.

I have used my T-599 on CW, SSB, and digital modes using tones on SSB at reduced power levels. For CW, tune up as normal and then reduce power with the carrier control. I have found that my 599 will not go below about 10 watts without detuning it a little. I always make sure the plate is dipped last for resonance. I am reluctant to detune the final circuit but I do move the load control to add more capacitance there (just a little) and redip the plate. I am considering using another, better (in my mind) approach if I find the ALC trick unsatisfactory - I haven't tried that yet.

For low power SSB the mic control does the same job. I started out with QRP and I still like QRP operation. I have used other transmitters with tubes and with transistors in exactly the same manner successfully. The tubes will be loafing along so you won't be hurting them at all. I am looking at some designs to use the transverter output to a final amp box that is purose built for QRP and just turn the finals OFF for that kind of fun. Slapping a 100 watt transmitter down to get QRP seems like overkill when a purpose built unit might be more reasonable. But we already have our Kenwood transmitters and they can be made to do QRP.

Go ahead and do it and have fun.

> My questions would be: is it better to tune and load the rig, as normal, and then reduce the output power by screwing back the output power by use of the carrier control switch or, tune and load the rig to full output power and, using the ALC minus voltage feature (minus alc via the skt on the back of the rig) reduce power that way. I know the rig is not designed for this type of operating at large, but I am trying to understand if it will shorten bottle life or have any impact at all on the final output stage running QRP for a period of time. The ultimate answer is run an 817 or similar but you work with what you've got !!

Will,

One other way to reduce the 830 to QRP levels is contained on page 20 of the TS-830 survival guide. In it, section 7.11 deals with one way to reduce power out to QRP levels. The text is, and I quote,"On SSB, turning down the mike gain is a poor way to reduce output power because doing so defeats the transmitter's ALC system. Thus, when you turn down the mic gain, you cannot assure any particular peak output level, and you're also turning down only the voice modulation content of your signal; the original carrier supression, unwanted sideband supression, misc transmitted noise, spurious and so forth are not adjusted "down" @ all, but remain as they were. As such, signal quality suffers. The best way to "turn down" the power of a TS830S.....is via the external ALC port onthe rig's rear panel. Providing an *djustable bias level to that port, ranging from 0 V DC to -10 V DC, will allow full-range power adjustment, down to zero output. This is accomplished with a 9 V transistor radio battery(POSATIVE terminal to chassis ground-ALC voltage supplies is negative) and a 1K ohm pot as wired as a voltage divider.

Tune up normally with poy adjusted for zero voltage @ ALC terminal, and should have about 100 watts out. With key down, adjust the pot until the power falls off to whatever power output you desire. Then, switch to SSB and your output will be that reduced level. DO NOT RETUNE anything on your rig, it's tuning will be just fine."

It closes by stating that the author(WB2WIK/6)had ran his rig that way for years and had no detrimental effects. It would provide all the audio punch and clarity, but @ reduced QRP levels. I have not tried it, but just thought I wouldf pass it along.

Hey folks, I'm new to the group but have been reading here for a couple weeks. I have a Kenwood TS-820S that I believe to be in good working order, though it has been in storage the past several years.
As I see several of you doing your own diagnostic and tech work I was wondering if anyone would care to make a recommendation on used oscilloscopes? I haven't touched one since high school and looking at them on ebay makes my head spin. Are there any functions/features that would lend themselves to working on these vintage radios? How about an RF generator? These are just some tools that I see are called for in some radio building kits which is where I would like to get my feet wet. Thanks for any advice.

I like the heathkit test equipment because the manuals are available and they are pretty easy to take care of.

I have 2 Heathkit scopes. IO-4550 and IO-4235. But for simple radio work most of the simpler (and more available) single channel scopes are good enough.

I use a Heathkit IG-102 signal generator.

Topic: 30291 Message: 30291

My TS-820 has decided to backfeed the 3.3vdc bias voltage with 5.8vdc. By process of elimination, I have found that this 5.8vdc is coming from the IF Unit.

With the IF Unit unpluged, the other RF1 voltage measurements in the radio are correct; 3.35vdc.

My 9.0vdc appears everywhere it should, the LEDs all function fine and I have 60ma bias. On Tun I can dip the Plate current, but I do nor register Drive with the meter switch in the ALC position.

I can adjust the Load to produce 225ma on CW, and I can easily peak the RF by fine tuning the Load and Plate controls. The radio transmits fine putting out 90 watts CW on 20 meters that I am able to tune to a SWR of 1.1:1

My external frequency display is working correctly, as is the VFO.

But I cannot hear a thing. Anybody have any ideas. Thanks

AE5UU

Rob,

If you want an oscilloscope with is on par (and better) with the build quality of the Kenwood hybrids, find yourself a Tektronix 465(A). These are build as a tank, dual channel and up to 150 Mhz. Have one myself and perfectly suitable to do all your measurements on the hybrids. One of the best scope ever made.
You will find many on ebay and they are pretty cheap: between 150-200 USS.

Sorry for being late, but it seems to me that -71 volts when transmitting on the final grids is too much, I mean bias is too high and the tubes are just biased close to the cutoff point - as I remember, bias voltage should be around - 50 volts when operating is SSB - does the BIAS control vary this voltage when transmitting ??? If it does not, check the bias voltage divider resistors / pot string -

Just my two eurocents..

Daniel,

No, the bias pot does not change the bias voltage between receive and transmit. Once the initial 60ma of idling current is set by adjusting the bias pot in USB or LSB mode the relay on the IF board controls the "level" of bias voltage applied to the final tubes.

Typical bias voltage levels to the final tube grids are -101VDC in receive and -65VDC in transmit with no RF applied to the final tubes.

A bias voltage of -71VDC is not bad.

Steve said the plate and screen voltage to the final tubes does not change between receive and transmit. The final tube plate and screen voltage will become "less" in transmit when the tubes conduct. If those voltage do not change even though the grid voltage does change, that indicates the tubes are not conducting.

For example, lets say the plate and screen voltages, as measured in receive, are as follows:

Plate - +950VDC
Screen - +265VDC

Switching to transmit the above voltage should become less with idling current flowing the the final tubes. Since Steve said the above voltage do not change, become less, when switching to transmit, that tells me the final tubes are not conducting. Steve did say the bias voltage does become "less negative" which is good. However, if the tube filaments are not emitting electrons, tubes are bad, the grid voltage can become "less negative" all day long but that will not cause the tubes to conduct. Electrons must be emitted from the filaments for conduction to occur. No electrons emitted from the filament, no electron flow will occur, regardless of how good the grid voltage is switching, and you will see no IP current, no change in plate and screen voltage, and no RF output in transmit.

Subject: [TS-520_820_530_830] mic hum

hi name is Ed i have a kenwood ts-830s i have been get a hum on ssb someone told me its the microphone its
not wired right the mic is a mc-50 4 pin he also sayed about keeping the grounds separate what is meant about
that i don't understand can someone help me so i can get rid of the hum.

thank you

Ed w9aba

Hi Ed,

There are two grounds on the 4 pin microphone into the 830. Pin 4 is for the shield of the microphone cable to the mike element. Pin 3 is for the PTT ground and the two grounds should not be connected together at the plug. The center wire of the shielded cable goes to Pin 1 and the other side of the PTT goes to Pin 2. If you have the owners manual you will find it on figure 2-1.

Good luck,

Mel, K6KBE

Reggie,

Ok...does the receive part of your rig seem to work OK? Does rig proper freq when changing bands and frequencies within the band? I am not an expert..as Mike(w6rkl), and several others are..but I've had my share of display problems with the 820S's. The DG-1 (counter/display unit) are nortorious. I would first try: Remove top and bottom connectors and clean pins and connectors of the DG-1 unit...it's the one with the wires going to the display tube, with DEOXIT or similar...apply/reapply connectors to pins several times...blow off with "canned air." Check for proper function. If still having problems, you can remove the DG-1 unit, remove and reinstall one board at a time after cleaning pins and connector(s) as above. Reassemble and see if it works. You may also have a malfunction of the VCO/PLL/PD unit. Try the above first....Mike and the others are better with dealing with the finer points of that unit. Check out pages #39, 40, & 41 of the TS820S service manual. Good luck.....

Has anyone come up with a paint that matches the front panel of the 530 or 830 with the same finish.. ie not glossy ? Or maybe where I could take it to get it matched and have them mix me a pint or so ?
I have a couple here I want to touch up the upper edges on.
I have the case paint, but not the front panel

thanks,

Hi,

I was going to ask how he could set the bias by seeing 60mA on the IP if the tubes were not conducting but I went back and read the initial post. If I had noticed the "no bias current" part I would have been all over that. He did a lot of work just to be sure.

Reggie,

Glad it was an easy fix. Mike's call is w5rkl..not w6rkl...there are numerous people here on this board that know just about everything about these fine KW hybrids. I have learned a great deal from them. As I said...the 820S's DG-1 unit can create numerous problems...the most common is getting some corrosion or gunk on the connectors/pins. Also...any liquid spilled on the top...is going to run right into the DG-1 unit...you don't want to go THERE!

Good Morning Group:

What follows is an update on the Kenwood Screen Saver project.

I've combed through the images on the Website and selected the photos that are appropriate in quality and minimum size. With that accomplished, I now call for any addition photographs, and / or graphics, including scans of the original Kenwood spec' sheets to complete our Screen Saver.

If you would like to have your contribution incorporated into the finished software, please don't hesitate to send it along to me (k3ssb@...) as an attachment. Please mention "Kenwood Screen Saver" in the message subject line.

With time devoted to the project limited to my "down" time, I forecast completion in approximately thirty days. At which time it will be uploaded to the Group Website for the enjoyment of all.

tnx es 73

Blimey - what happened to the plate choke?

I find it hard to believe it has overheated like that and yet the output devices seem intact. How do people do this to a radio??

Anyhow, well done on saving another of these beautiful hybrids from the spares box.

That's what happens when consistent excessive current flows in the final tubes.

A choke that bad, more than likely the four 20 ohm cathode resistors are also bad.

As Gordon said in a recent response, you can rewind the coil with #34 enamel wire.

Aloha Gordon,
I found Rust-Oleum 7754 Anodized Bronze a very close match it is not glossy and in small area's it works fine. I have only found it in a spray can but being here in Hawaii we are lucky if we can get anything hi hi.

Hi Roland,
thanks for the info. I'll get a can and try it out.
I'll let you know how it works out.

Ed,

Did you try the recommendation(s) using the "MONI" push button to listen to your actual transmit audio? If you have not done that then I recommend you do that first before you do anything else.

Also, what microphone are you using? The ground return for the microphone "element" should not be connected "directly" to ground but rather through a .01ufd disc capacitor. Hum and/or distortion in the transmit audio can occur if you do not keep the ground return of the microphone "element" above ground through a .01ufd capacitor.

30316. TS-820 IF board and 3.3vdc bias voltage

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-03-21 19:11:40 UTC
From: ae5uu
Topic: 30316 Message: 30316

Group,

I am having difficulties with the 3.3vdc bias and with the IF board. I may have other problems as well, but I have started here:

Problem summary, Kenwood TS-820

External Symptoms

1) On tune up, with the MODE switch set to TUN and the Meter switch set to ALC, there is no Drive reading registered. And yet, it is easy to peak or eliminate output power with the Drive control, when done later in the tuning process.
2) RF GAIN control reduction does not reduce audio output and does not move the Meter CW.
3) The radio tunes up for full output, after blindly maximizing output with the Drive control at the end of the tune up process. Receive, on the other hand, seems noisier than before I started having this problem, and the ATT has effect, but seeming less than before.
4) Everything else works correctly.

Internal Symptoms

1) While the 9.0vdc bus sets properly with VR-4 on the AF-AVR board, the 3.3vdc bus reads 5.92vdc, no matter the position of VR-1 on the same board. When the IF board is unplugged, the voltage at other access points in the radio reads 3.3vdc correctly.
2) Assuming, perhaps rightly or wrongly, I have a problem on the IF board at Q-15 or Q-16, I focused on this area.
3) The voltages at Q-15 are correct. The voltages at Q-16 are not, and some neighboring component pieces are not performing properly.
4) Q-16 reads as follows: Base -5.86 It should read -3.0
Emitter -5.85 It is within spec.
Collector 6.54 It should read 0.0

Maybe I am picking the voltages of the schematic incorrectly, they are rather small, but I don't think so.

I have some rather strange readings along the voltage path for both Q-16 Base and Q-16 collector.

The Q-16 Base path is
Q-16B.....-5.85.....R-146.....-5.85.....D-18.....-5.85.....D-19....-5.85.....-6vdc bus. It should read -3.0vdc.
So it is as if Q-16B is connected directly to the -6vdc source (reads -5.85vdc in my radio)

The other path for Q-16B runs
Q-16B.....-5.85.....R-146.....-5.85.....L-11.....-5.85.....AGO at the pin

Q-16 Collector path is Q-16C.....6.56.....R-145.....6.56......AGC at the pin. At the transistor it should read 0.0vdc.

The other path is Q-16C.....6.54.....C-142.....-6.56.....Q-16 Base (which should read -3.0vdc)

The resistors mentioned above test within spec. I have not been able to test the diodes D-18 and D-19, but the voltage which passes through them both,wired in series, reads -5.85, which cannot be correct.

So in summary, perhaps Q-16 Base and Emitter are shorted. And the Q-16 Collector reading of 6.54vdc isn't right.

If anyone is intimately familiar with the TS-820 IF board, I sure would appreciate your help

73,

Russell

If you know the mike is OK using it to find the problem is an exorcize in futility.

You need to use an audio signal generator and a scope to look at the signals.

When the DRIVE control is peaked you will get the most antenna noise in the receiver.

With the unit in RECIEVE try moving the DRIVE control from CCW to CW. Where the noise peaks is where you are in the proper position.

Ed & Mike,

My 830S is right in front of me.....the switches are labeled "FIX" "MONI" "RF ATT" they are to the right of the MIC/CAR control and left of the vfo. I use the MONI often to check voice quality.

Topic: 30321 Message: 30321

Hi Folks,

Just a quick question that pertains to the 6146B tube and not the QRO modification mentioned herein.

I am in the process of modifying a Yaesu FT-101 to work with 6146B tubes. I've installed the tubes, and the best output I can get (on 80 meters) is about 60 watts, with the screen grid running at about 170 volts in transmit. This voltage is provided by a dedicated winding on the transformer.

I would like to increase the screen voltage to around 220 volts (or therabouts) to generate a bit more RF. (Quick) tests that I have made with a high wattage variable resistor have indicated that the output can be increased to about 115 watts, nothing to sneeze at!

One possible problem with this approach is that I'm generating the 220 volts on transmit with a voltage divider hooked to the low voltage line - about 360 volts in the receive mode. While I can adjust my screen grid voltage to around 220 volts in transmit (when more power is being drawn from the power transformer), the voltage will jump up close to 300 volts when in the receive mode.

Now, the data sheets for the 6146 specify a maximum of 250 volts on the screen grid. If the 6146's are biased off in the receive mode, will this extra potential hurt the tubes as they won't actually be conducting, right(or wrong)??

The only other option would be some kind of zener regulation.

Any thoughts from you tube gurus??

I would run it stock. You're only talking a few db difference on the receiving station's S meter. Look for a SB200 amp or a better antenna.

Bob,

That checks out, but it is hard to tell the difference in receive with the Drive control set at 1200, 1300, and 1400. I guess if you average at 1300, that does correspond to the maximum output of the transmitter section.

When the DRIVE control is peaked you will get the most antenna noise in the receiver.

With the unit in RECIEVE try moving the DRIVE control from CCW to CW. Where the noise peaks is where you are in the proper position.

Subject: [TS-520_820_530_830] TS-820 IF board and 3.3vdc bias voltage

Group,

I am having difficulties with the 3.3vdc bias and with the IF board. I may have other problems as well, but I have started here:

Problem summary, Kenwood TS-820

External Symptoms

1) On tune up, with the MODE switch set to TUN and the Meter switch set to ALC, there is no Drive reading registered. And yet, it is easy to peak or eliminate output power with the Drive control, when done later in the tuning process.

2) RF GAIN control reduction does not reduce audio output and does not move the Meter CW.

3) The radio tunes up for full output, after blindly maximizing output with the Drive control at the end of the tune up process. Receive, on the other hand, seems noisier than before I started having this problem, and the ATT has effect, but seeming less than before.

4) Everything else works correctly.

Internal Symptoms

1) While the 9.0vdc bus sets properly with VR-4 on the AF-AVR board, the 3.3vdc bus reads 5.92vdc, no matter the position of VR-1 on the same board. When the IF board is unplugged, the voltage at other access points in the radio reads 3.3vdc correctly.

2) Assuming, perhaps rightly or wrongly, I have a problem on the IF board at Q-15 or Q-16, I focused on this area.

3) The voltages at Q-15 are correct. The voltages at Q-16 are not, and some neighboring component pieces are not performing properly.

4) Q-16 reads as follows: Base -5.86 It should read -3.0

Emitter -5.85 It is within spec.

Collector 6.54 It should read 0.0

Maybe I am picking the voltages of the schematic incorrectly, they are rather small, but I don't think so.

I have some rather strange readings along the voltage path for both Q-16 Base and Q-16 collector.

The Q-16 Base path is
Q-16B.....-5.85.....R-146.....-5.85.....D-18.....-5.85.....D-19....-5.85.....-6vdc bus. It should read -3.0vdc.

So it is as if Q-16B is connected directly to the -6vdc source (reads -5.85vdc in my radio)

The other path for Q-16B runs
Q-16B.....-5.85.....R-146.....-5.85.....L-11.....-5.85.....AGO at the pin

Q-16 Collector path is Q-16C.....6.56.....R-145.....6.56.....AGC at the pin. At the transistor it should read 0.0vdc.

The other path is Q-16C.....6.54.....C-142.....-6.56.....Q-16 Base (which should read -3.0vdc)

The resistors mentioned above test within spec. I have not been able to test the diodes D-18 and D-19, but the voltage which passes through them both,wired in series, reads -5.85, which cannot be correct.

So in summary, perhaps Q-16 Base and Emitter are shorted. And the Q-16 Collector reading of 6.54vdc isn't right.

If anyone is intimately familiar with the TS-820 IF board, I sure would appreciate your help

73,

Russell

Bob,

I guess I wasn't clear; the Drive control gives both maximum receiver noise and maximum transmit power at a setting of 1 o'clock. My main problem, perhaps the one to which the others relate, is the 5.92vdc on my 3.3vdc bus. Do you think that I should pull Q-16 from the IF board an measure it for a short between the Base and the Emitter?

Now that you have idling current, have you checked R15 (56K 1/2 watt) resistor on the Rectifier Unit? If it's value is out of tolerance then you will experience loss of ALC in TUNE mode.

Have you tried tuning the 530 up in CW mode? To make it easy, remove any plug you may have inserted into the rear panel's "CW" socket. You do not need a CW key plugged into the CW socket to tune the 530 up in CW mode.

When tuning the 530 up in CW mode you must understand that "full final tube screen voltage" is applied to the final tube!! Therefore, keep your key down times short and monitor the IP current at ALL times.

1. Place MODE switch to CW and LOAD control fully CCW.
2. Connect 530 to dummy load
3. Set CAR control between 9 and 10 o'clock
4. Flip the SEND switch UP (switches to transmit)
5. Adjust the DRIVE control for a peak IP meter indication
6. Quickly adjust the PLATE control for a "dip" (reduction) in IP current
7. Switch meter to RF and adjust the LOAD control for a peak RF indication.
8. Flip the SEND switch DOWN (returns 530 to receive)

That's enough for now. Do you see any RF output on the RF meter switch setting? We'll continue more once you follow these simple CW tune up procedures. The key here is to determine whether or not the 530 is producing any RF output.

73s
Mike

That is assuming the receiver's COIL Unit is adjusted for maximum input signal. One can peak the RF drive with the DRIVE control and still have a lower peak receive signal if the receiver's COIL PACK adjustments are not adjusted properly.

One more thing. This assumes that the rear panel "SG" switch is set to "ON" and not "OFF".

Ed,

? The ground return for the microphone "element" should not be connected "directly" to ground but rather through a .01ufd disc capacitor. Hum and/or distortion in the transmit audio can occur if you do not keep the ground return of the microphone "element" above ground through a .01ufd capacitor.

73smessage have been removed]
>

  This is the first time I have heard that info!!? Every Mic I have used or serviced (public safety dispatch centers) cable shield ends have been grounded to chassis ground ! Tracing out any separate mic return lead also ends at chassis ground potential.

[Non-text portions of this message have been removed]

Ok, I've removed the key from the cw jack. I set the mode to cw, load at minimum, car between 9 and 10, and switch to send, no alc to peak. Meter switch to ip mode, only reading 60ma idle current. No RF. I know that when I used to hit send, the meter would "bounce up" a bit and return to nil. Now it doesn't do that anymore. I also notice that the receive is acting funny. The marker signal is very weak and sometimes isn't there at all. I remember once the other day when tuning in the marker signal, that it faded out to barely audible with the volume all the way up. The cw sidetone is plenty loud. It's as if there isn't anything there for the finals to work with signal wise.

Thanks again
73
Steve

Topic: 30332 Message: 30332

Hello everyone, I need to know the easiest way to connect the receive out from the 820s to the receive input jack on the 784b, which is an RCA jack. The only RCA jack that comes close is the if out for a station monitor. According to the directions for the 784b, the receive signal(audio)is usually from either the speaker out jack or the headphone jack. Neither of which, is an RCA. Thank you very much for any help you can give. 73's to all, Charles Kj4fcj

Go to Radio Shack and buy a RCA to phone plug adapter.

That may be so with commercial gear. However, we are talking about a Kenwood 830 not a Gates, RCA, or some other commercial transmitter etc. I don't doubt your word so please don't think I am.

Kenwood, on the other hand, clearly states not to use the same ground for PTT and microphone element return. The operator manuals for the 520, 530, 820, and 830 clearly show this.

Steve,

Have you taken voltage readings on the driver tube to see if there is any change in voltages between receive and transmit with the new tubes? That's where I would start.

It's quite possible the relay on the IF Unit may be causing the problem. Clean the plugs on the IF and AF units, one at a time, with contact cleaner, making sure the plugs seat flush on the boards.

When you rotate the RF gain control CCW, in receive, does the meter rise and eventually peg full scale to the right? This is what it should do. Rotating the RF gain control CW should cause the meter to fall back to zero. Again, that's what it should do.

No RF. I know that when I used to hit send, the meter would "bounce up" a bit and return to nil. Now it doesn't do that anymore. I also notice that the receive is acting funny. The marker signal is very weak and sometimes isn't there at all. I remember once the other day when tuning in the marker signal, that it faded out to barely audible with the volume all the way up. The cw sidetone is plenty loud. It's as if there isn't anything there for the finals to work with signal wise.

Morning Steve,

I just wanted to ensure the bias voltage was switching like it should between receive and transmit and vice verse.

You can check the driver bias voltage at the RF Unit plug 8 pin 1 and ground. In receive the voltage should be approximately -51VDC and in transmit +.4VDC.

Make sure the RF ATT push button on the front panel is not pressed. The receive signals flows through the RF ATTN push button switch. The CAL (Marker) signal does not flow through the RF ATTN switch. The PLL Unit's "MKR" (CAL) signal flows directly to the RF Unit through plug 4 pin 2.

I recall seeing detalis of such a conversion over on the Fox Tango Yahoo
(IIRC) group...
I think it was a complete article in the files section.
Perhaps a quick check there could help as well.

From: w5rkl
Topic: 30338 Message: 30339

The maximum screen voltage and current for a single 6146B is 250VDC at 12ma.

The typical operating screen voltage and current levels depends on the class of amplifier the 6146B is operating in.

Mike,

I feel it most likely that Q-16 is bad, shorted between the Base and the Emitter. Does this seem reasonable to you?

That is assuming the receiver's COIL Unit is adjusted for maximum input signal. One can peak the RF drive with the DRIVE control and still have a lower peak receive signal if the receiver's COIL PACK adjustments are not adjusted properly.

Russell,

I assume you are talk about Q16 on the IF board. If so what voltage do you see on IF board plug IF3 pin 11?

Hello Paul,

I'll assume you replaced "both" HV filter capacitors and made sure you wired them in "series"! You should replace both HV filter capacitors even if only one failed.

Make absolutely sure you wired the capacitors correctly and not backwards and made sure you connected them correctly. This is very important otherwise you will cause further damage to the HV supply and possibly other components.

You should also check the 4 diodes in the HV supply. If one of the HV filter capacitors blew then it can easily take out one or more of the diodes in the HV supply. The diodes are D1 thru D4 with four 470K 1/2 watt resistors, R1 thru R4, across each diode. You can use 1N4007 (1KV at 1 amp) diodes as replacements. Replace all 4 of the diodes even if only one appears to be blown. Diodes, like resistors, are cheap.

Mike,

Pin 11 on the IF Board IF3 (AGC) measures +6.56vdc

30349. A MILESTONE FOR ME WITH TS-530S

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)

Its probably no big deal to most here but last night I tried my 530S in receive mode - I am not licenced yet so tx is out for a while. I only had a basic plain wire antenna so did not expect to hear anything..and I was not disappointed!.Actually I did hear something very faint I think on 40m. although it was probably wishful thinking on my part. I have had no guidance with using a ham radio and am taking it slowly using the manual and learning as I go.

However it was great to actually hear the rig making sounds as I had fears that it may well have been DOA.

Now my enthusiasm has been given a shot and tonight I plan to try sorting the antenna bit more and see if I can pick up something more interesting.

I might even try the TS-520S that I also have - its in much nicer condition but again I have never had it switched on yet.

I'll need to get a decent set of headphones sooner rather than later if I am not going to upset the XYL...any suggestions welcome.

Try 40M between 6PM and 10PM local time. Yon may not hear much phone activity. Most 40M activity is CW between 7000 and 7100.

Then try 75M phone after 10PM local time. Look between 3800 and 4000. Also check between 3600 and 3800 but activy there will be more sparse

This could be because the radio had been in storage for a few years.

What can happen is that the dielectric within the caps deteriorates during storage, meaning a heavy leakage current will flow for a while until the dielectric re-forms. Unfortunately, all too often the caps will overheat due to this leakage current before they get a chance to 'heal up'. The failure can sometimes be explosive, as I have witnessed. (Not in a Kenwood, you may be pleased to hear!)

Replace both caps with similar capacity units, and observe the voltage rating - they should be rated at 500v.

New caps of the correct physical size can be ordered from our friend Ken:

Check 40M in the evening between 6PM and 10PM local time. You may not hear much phone activity. Most 40M activity is CW between 7000 and 7100.

Then try 75M phone after 10PM local time. Most activity will probably be found between 3800 and 4000. But you might find some Extra Class people between 3625 and 3800.

This weekend is a major SSB contest. You can try 20M during the day. You should hear a lot of activity.

Subject: [TS-520_820_530_830] A MILESTONE FOR ME WITH TS-530S

Its probably no big deal to most here but last night I tried my 530S in receive mode - I am not licenced yet so tx is out for a while. I only had a basic plain wire antenna so did not expect to hear anything..and I was not disappointed!.Actually I did hear something very faint I think on 40m. although it was probably wishful thinking on my part. I have had no guidance with using a ham radio and am taking it slowly using the manual and learning as I go.

However it was great to actually hear the rig making sounds as I had fears that it may well have been DOA.

Now my enthusiasm has been given a shot and tonight I plan to try sorting the antenna bit more and see if I can pick up something more interesting.

I might even try the TS-520S that I also have - its in much nicer condition but again I have never had it switched on yet.

I'll need to get a decent set of headphones sooner rather than later if I am not going to upset the XYL...any suggestions welcome.

That's twice the voltage that should be present on IF3 pin 11.

What voltage do you see at AF AVR Unit plug AF2 pin 6?

Topic: 30316 Message: 30354

Mike,

I see 5.92 volts on the AF-AVR board AF2 pin 6, instead of the proper 3.3vdc. When I unplug the IF Unit, the voltage drops to 3.3vdc, and can be measured at that level everywhere it should be in the rest of the radio (excepting the IF Unit of course.) This is what sent me to the IF unit where I found Q-15 to have the correct voltages, but Q-16 base = -5.85, Q-16 emitter = -5.85, and Q-16 collector = =+6.54. While the emitter voltage is correct, the base is wrong, reading the same as the emitter, and perhaps this is causing the voltage reading on the collector to be wrong as well. If this transistor is bad (base shorted across to emitter), it would perhaps be the cause of my problems.

Also when I was on the air this morning to a friend in MN, he told me that my audio was greatly distorted. We got it right by lowering my MIC control all the way to 8 o'clock, where formerly it was correct at 12 o'clock. The pre-amp on the mic was unchanged from usual and the Processor was off as usual.

Incidentally, I have 9.0vdc from the AF-AVR Unit AF1 Pins 1 & 2, and it is present everywhere in the radio that it should be, with or without the IF board being plugged in.. Also all LED lights function correctly.

73,

Russell Nilson

ALLAN,
have a look at setting up a better ANTENNA , as you are in KIWI LAND , 3.5 Mhz to 3.8Mhz (day time)and 7.0Mhz t0 7.2Mhz & 14.0Mhz-14.300 (at night)will be best .

A set of good head Phones will help keep the XYL happy, I picked up a set at the local FLEA Market for $10.00 and theybwork well.

Your ANTENNA is crucial . the better the ANTNNA the more you hear. HAsve a look at DX ZONE and they have antennas for all bands and configerations that you can build yourself.
I currrently have a HF DOUBLET feed with open wire feeder which tunes from 3.5Mhz to 28.5Mhz.

Check 40M in the evening between 6PM and 10PM local time. You may not hear much phone activity. Most 40M activity is CW between 7000 and 7100.

Then try 75M phone after 10PM local time. Most activity will probably be found between 3800 and 4000. But you might find some Extra Class people between 3625 and 3800.

This weekend is a major SSB contest. You can try 20M during the day. You should hear a lot of activity.

  Its probably no big deal to most here but last night I tried my 530S in receive mode - I am not licenced yet so tx is out for a while. I only had a basic plain wire antenna so did not expect to hear anything..and I was not disappointed!.Actually I did hear something very faint I think on 40m. although

it was probably wishful thinking on my part. I have had no guidance with using a ham radio and am taking it slowly using the manual and learning as I go.

  However it was great to actually hear the rig making sounds as I had fears that it may well have been DOA.

  Now my enthusiasm has been given a shot and tonight I plan to try sorting the antenna bit more and see if I can pick up something more interesting.

  I might even try the TS-520S that I also have - its in much nicer condition but again I have never had it switched on yet.

  I'll need to get a decent set of headphones sooner rather than later if I am not going to upset the XYL...any suggestions welcome.

Hi Alan,
Listen to 3.850 at 5:30PM NZ time and 7.083 at 6:00 NZ time, these are two nets which are on every night. As the guys give signal reports from all over ZL, you should get some idea of what you are should be hearing.
Cheers,
John

I agree Russell. It does appear that Q16 is bad. I don't have a direct NTE replacement for Q16. I would replace Q16.

Q16's Emitter should be -6VDC and Q16's Base should be -3VDC which makes Q16's Collector 0VDC.

I have not measured Q16's voltages. The voltages given are from Kenwood's service manual IF Unit schematic.

Q15 and Q16 along with D18 and D19 is/are the receiver's AGC circuit/amplifiers along with fast attack slow decay components.

Since the IF amplifier Q1 is used in both receive and transmit, it stands to reason, distortion in receive will translate to distortion in transmit.

30358. TS-530 Project...

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-03-23 01:32:12 UTC
From: n8ydadam
Topic: 30358 Message: 30358

Hello, all. I just picked up a 530 that a friend had given up on. He'd lost output (has drive, but no final), and it's the same with new tubes.

While looking over the rig, I noticed that a cap has crumbled to bits on the antenna relay board, under the final cage. Could this be the problem?

The next question.... Anyone know the value of the caps on the relay board, or have info on it? It's a ceramic disc, but I believe there are two there. My service manual shows a pinout for the relay, but I'm unable to find the rest in the schematics.

Thanks!
Adam, N8YD

Sounds like the band switch output part is clocked wrong.
Which caps are you referring to?
I know the coil has a .01 across it for the relay

Adam,

Do you mean the "final unit?" X56-1380-00? Is iit the one that the final tubes fit into...on the rear left corner with radio bottom up and VFO facing you?

It's a small (1x1.5" maybe) board on a relay, mounted next to the final board. The board is actually inside the final cage, and the relay protrudes below the chassis with a metal cover.

Topic: 30358 Message: 30363

I have one of these relay boards in my hand. The board number on the relay board I has is J25-3015-0 which is different than the 530 service manual board number on page 11 which is J25-3015-04.

However, the board I have has 2 disc caps.

Looking at the 530 service manual, page 11, top right "foil side" picture, there are 4 terminal on the left and 4 terminals on the right.

Looking at the left side, second terminal from the top left is "ground" (shield from small coax). A small disc capacitor is connected from the second terminal from the top left to the second terminal from the top right. This capacitor is a "103" or ".01ufd" capacitor.

Looking at the left, 3 terminal from the top, another capacitor lead connects to this 3rd terminal from the top. This capacitor is marked "101" or "100pf".

I hope this helps.

Hello, Mike. The 100pf is what I'm looking for. Thanks! The mentioned diagram on page 11 is the only reference I've seen in the manual. Is there more?

Subject: [TS-520_820_530_830] Re: TS-530 Project...

I have one of these relay boards in my hand. The board number on the relay board I has is J25-3015-0 which is different than the 530 service manual board number on page 11 which is J25-3015-04.

However, the board I have has 2 disc caps.

Looking at the 530 service manual, page 11, top right "foil side" picture, there are 4 terminal on the left and 4 terminals on the right.

Looking at the left side, second terminal from the top left is "ground" (shield from small coax). A small disc capacitor is connected from the second terminal from the top left to the second terminal from the top right. This capacitor is a "103" or ".01ufd" capacitor.

Looking at the left, 3 terminal from the top, another capacitor lead connects to this 3rd terminal from the top. This capacitor is marked "101" or "100pf".

I hope this helps.

You did not mention this so I will assume there is 60ma of final idling current with either the microphone PTT button pressed or the SEND switch flipped UP, showing on the IP meter with the MODE switch set to USB or LSB.

When you peak the drive then switch the meter to IP and adjust the PLATE control for a dip in IP current, do you see any dip at any position of the PLATE control?

I tend to agree with Gordon, it's quite possible the band switch shaft is out of sync with the final amplifier switch assembly S22.

Switch assembly S22 is the ONLY switch wafers inside the final amplifier enclosure. The shaft of S22 has "2" flat spots.

With the 530 front panel facing you, set the band switch to "10". with the final amplifier cover removed, look at the rear of the plastic coupler that connects the long band switch shaft to the plastic couple. You should see a flat spot on S22 shaft vertically on the "right". The other flat spots on S22's shaft should be on the "bottom". If this is NOT how S22's shaft is resting with the band switch set to 10, I agree with Gordon, switch S22's shaft is "out of sync" with the band switch. I just repaired a 530 that had this exact problem.

You have to look closely at the shaft of S22, the coupler may be slide too far onto the S22's shaft to see the flat spot.

The set screws are "1.5mm" hex wrench. If you only have U.S. hex wrenches they will NOT fit the set screws. Most hardware stores sell a complete long shaft set of metric hex wrenches for $6 or so.

HI Adam,

Unfortunately I do not know of any other reference or individual diagram showing the relay other than the main schematic.

Gordon's right, the 103 (.01ufd) cap is connected across the relay coil. That's the disc cap that connects between the second terminal from the top left to the second terminal from the top right.

The heavy solid wire connected to the 3rd terminal from the top left, same terminal the lead of the "101" capacitor is connected to, is the transmitter's PI Network "output" and connects to the antenna SO-239 but ONLY when the relay is energized.

The relay is a "solenoid" type relay. The relay is NOT on a socket, it's soldered to the board. You cannot "manually" activate the relay with your finger with the relay's plastic cover off. You must apply 12VDC to the relay coil to see how the relay works. You can do this removing plug 6 on the AF Unit board and applying 12VDC to plug 6 pin 6 and chassis ground. The relay connects directly to plug 6 pin 6. You will notice, when the relay is energized, the 2 copper strips move UP and DOWN, UP when the relay is energized and DOWN when the relay is NOT energized. Be very careful when removing the plastic cover to ensure you do not damage or bend any of the relay terminals.

DO NOT attempt any of these steps with power applied to the 530!! Remove ALL power, discharge the HV filter capacitors, BEFORE attempting any work inside the 530.

Date: 2011-03-23 03:47:34 UTC
From: Russell Nilson
Topic: 30316 Message: 30367

Mike,

Thank you for the help. The replacement numbers for various components in the AGC circuit are as follows, in case anyone else develops this problem:

Q-15, Q-16 Kenwood number = 2SC733(Y) Replaced by NTE199
Q-1, Q-2, and Q-3 Kenwood number = 3SK35(GR) Replaced by NTE222
D-18, D-19 Kenwood number = 1N60 Replaced by CDSH270
D-20, D21 Kenwood number =
1S1555 Replaced by NTE177

Thanks to Charles and others in our group for some of these numbers. I tried mouser.com for the rest and came up short. But by going directly to the nteinc.com website, it was easy. Once I had the replacement numbers, mouser.com had them all.
They cost next to nothing, with the exception of the NTE222 (which I hope not to need; I haven't examined that part of the board yet), which cost $12 each.

Strangely, I discovered today that Mouser is only 35 miles my home here in the DFW area.

I agree Russell. It does appear that Q16 is bad. I don't have a direct NTE replacement for Q16. I would replace Q16.

Q16's Emitter should be -6VDC and Q16's Base should be -3VDC which makes Q16's Collector 0VDC.

I have not measured Q16's voltages. The voltages given are from Kenwood's service manual IF Unit schematic.

Q15 and Q16 along with D18 and D19 is/are the receiver's AGC circuit/amplifiers along with fast attack slow decay components.

Since the IF amplifier Q1 is used in both receive and transmit, it stands to reason, distortion in receive will translate to distortion in transmit.

Ok. I have proper idling current, and the bandswitch shaft is correct, if I understand you correctly. (Flat spots on the Long shaft to front panel are vertical, while the section inside the cage are horizontal.

The cap I'm working with would be the one from the relay to the Pi-network. Unless what I had wasn't a high enough voltage rating, upon testing it immediately cooked.....

Would that point to another issue?

Subject: [TS-520_820_530_830] Re: TS-530 Project...

You did not mention this so I will assume there is 60ma of final idling current with either the microphone PTT button pressed or the SEND switch flipped UP, showing on the IP meter with the MODE switch set to USB or LSB.

When you peak the drive then switch the meter to IP and adjust the PLATE control for a dip in IP current, do you see any dip at any position of the PLATE control?

I tend to agree with Gordon, it's quite possible the band switch shaft is out of sync with the final amplifier switch assembly S22.

Switch assembly S22 is the ONLY switch wafers inside the final amplifier enclosure. The shaft of S22 has "2" flat spots.

With the 530 front panel facing you, set the band switch to "10". with the final amplifier cover removed, look at the rear of the plastic coupler that connects the long band switch shaft to the plastic couple. You should see a flat spot on S22 shaft vertically on the "right". The other flat spots on S22's shaft should be on the "bottom". If this is NOT how S22's shaft is resting with the band switch set to 10, I agree with Gordon, switch S22's shaft is "out of sync" with the band switch. I just repaired a 530 that had this exact problem.

You have to look closely at the shaft of S22, the coupler may be slide too far onto the S22's shaft to see the flat spot.

The set screws are "1.5mm" hex wrench. If you only have U.S. hex wrenches they will NOT fit the set screws. Most hardware stores sell a complete long shaft set of metric hex wrenches for $6 or so.

The TS-530 and TS-830 should have, with the band switch in the 10 mhz (not 10 meters) position, one set of flats facing right (out) and the other set facing DOWN.
The output band switch has two flats that MUST match the set screws. it can be easily put 18-0 degrees out !!

Alan;
Since you are new to the hobby, in addition to the info from others,
normally on
7MHz or the 3.8-4.0 MHz bands you will need to be in LSB for voice. 14MHz
and
up frequencies you should normally be in USB mode for voice. Of course, CW
mode
is the same for all of the bands.

For listening, a standard dipole is probably your best bet for now, and even
one
set up for 7.0MHz will work fine for receive with the Kenwood hybrids on the
bands.

Good luck and enjoy.

Adam,

No, it appears you did not understand what I said. I never said or even referred to "the flat spots on the long shaft to the front panel". I said the flat spots on the shaft of the only switch assembly (S22) "inside the final amplifier enclosure".

I also said to set the band switch to "10". The front panel band switch markings are from lower right, clockwise (CW), 1.5, 3.5, 7, 10, 14, 18, 21, 24.5, 28, and 29. When I said set the band switch to "10" I meant exactly that, "10" on the front panel. If anyone assumes I meant "10 meters" then that assumption would be wrong.

I said

"I also said to set the band switch to "10". The front panel band switch markings are from lower right..."

I meant "Lower left", typo, meaning rotating clockwise from lower left to lower right.

Thanks Chuck (and the others who responded with some words of advice)

I worked out the LSB/USB issue last night and managed to pick up a couple more very faint transmissions but I will definitely have to do something about the antenna. It's a bit trial and error at the moment until I can get someone to sit with me and explain some of the features on the radio

We are in a fairly deep depression where we live and even cellphone coverage is marginal so I suspect the hookup wire is just not up to the job. I'll try a longer and higher version at the weekend when I have more time on my hands.

I'll do a bit of a Google tonight and see what I can find to help me build a halfway decent antenna - thanks for suggesting I try a 7.0MHz.

If I am still struggling with receiving a decent signal I'll take the rig across to the beach at Easter where reception should be much better.

Lots to learn but I think I am going to enjoy it. Now all I want is a Kenwood TM255E to cover VHF and I "should" be happy for a while....maybe judging by the gear in some shacks

To try and simplify things... I see two little black nubs on part of the band switch inside the final cage. These appear to be what hold the switch's position. When set for 10MHz/30m where should these be in relation to the front panel?

Allan,

the more wire and the higher you can get it above the ground, the better.

With wire antennas the 2 basics are length and height.

As i said try DX ZONE and you will find literilly hundreds of antennas to make.

Topic: 30358 Message: 30377

Adam,

Before doing any visual inspections and attempting to correct any out of sync band switch alignment, remove ALL power cable, ensure ALL power supplies are discharged, and take your time. If you attempt to do any of the following in a hurry you can make matters worse than they already are. If you do not understand any of this, ask questions. Do NOT assume anything. Switch "S22" is "inside" the final amplifier and it is the ONLY switch assembly inside the final amplifier.

Remove the top and bottom covers then remove the top cover off of the final amplifier enclosure.

Remove final tube V1, the front 6146. You cannot see the coupler and S22 switch assembly inside the final amplifier clearly without removing V1.

Look, from the right side of the final amplifier enclosure, through the space occupied by V1. You will see the mounting bracket that supports S22. You will also see the plastic coupler that connects the long band switch shaft to S22 switch assembly inside the final amplifier enclosure.

There are "4" small "1.5mm" dark colored "hex" sets screws, "2" rear set screws that hold the plastic coupler to S22's shaft and "2" front set screws that hold the plastic coupler to the long shaft to the front panel knob.

Look closely as S22 shaft, the portion that slides into and is held to the plastic coupler by the 2 "rear" 1.5mm small dark colored set screws. You should see 2 flat spots on S22's shaft.

With the band switch knob set so the band switch knob points "exactly" at "10" on the front panel, one of the flat spots on S22 shaft MUST be exactly "vertical" on the right. The other flat spot on S22 shaft MUST be exactly "horizontal" on the "bottom", again with the front panel band switch knob pointing "exactly" at "10" on the front panel! This is the "correct" alignment of the entire band switch system/assembly. Any thing different than this means the band switch system/assembly is "out of sync"!

The band switch "will" rotate "continuously 360 degrees" in either direction! There are "NO" stops to the band switch!

You will need a "metric" hex tool, size "1.5mm". Do NOT attempt to remove/loosen the coupler set screws with any tool but a 1.5mm hex tool. If you do you will permanently damage the set screws.

Do NOT loosen the plastic couplers' front set screws on the long band switch shaft unless you are replacing a broken coupler!! If the coupler is NOT cracked or broken and you have found S22 is out of sync with the rest of the band switch system/assembly, then the only set screws you need to loosen are the 2 "rear" set screws.

Do NOT over tighten the set screws! Over tighten set screws will "break" or cause the coupler to "crack" at the set screws! If this occurs you will have to replace the coupler! You do NOT have to replace the coupler simply because it's old. As the old saying goes, "if it ain't broke don't fix it!!!".

The end result, when this alignment is done properly, the front panel band switch knob pointing exactly at 10 with results in S22's shaft flat spots be exactly vertical on the right side and exactly horizontal on the bottom. Any other S22 shaft flat spot alignment with the band switch knob pointing to exactly 10 on the front panel will be wrong!

Thanks for some clarification, Mike. No problem on unplugging the set. I hope to be able to use it if I get it figured out. ;-)

I wasn't quite sure on the orientation of the shaft for the band switch, but now I think I got it.

Do you happen to know the voltage ratings for the caps on the antenna relay board? I have a recap kit, but it's only electrolytics.

Adam

Adam,

Before doing any visual inspections and attempting to correct any out of sync band switch alignment, remove ALL power cable, ensure ALL power supplies are discharged, and take your time. If you attempt to do any of the following in a hurry you can make matters worse than they already are. If you do not understand any of this, ask questions. Do NOT assume anything. Switch "S22" is "inside" the final amplifier and it is the ONLY switch assembly inside the final amplifier.

Remove the top and bottom covers then remove the top cover off of the final amplifier enclosure.

Remove final tube V1, the front 6146. You cannot see the coupler and S22 switch assembly inside the final amplifier clearly without removing V1.

Look, from the right side of the final amplifier enclosure, through the space occupied by V1. You will see the mounting bracket that supports S22. You will also see the plastic coupler that connects the long band switch shaft to S22 switch assembly inside the final amplifier enclosure.

There are "4" small "1.5mm" dark colored "hex" sets screws, "2" rear set screws that hold the plastic coupler to S22's shaft and "2" front set screws that hold the plastic coupler to the long shaft to the front panel knob.

Look closely as S22 shaft, the portion that slides into and is held to the plastic coupler by the 2 "rear" 1.5mm small dark colored set screws. You should see 2 flat spots on S22's shaft.

With the band switch knob set so the band switch knob points "exactly" at "10" on the front panel, one of the flat spots on S22 shaft MUST be exactly "vertical" on the right. The other flat spot on S22 shaft MUST be exactly "horizontal" on the "bottom", again with the front panel band switch knob pointing "exactly" at "10" on the front panel! This is the "correct" alignment of the entire band switch system/assembly. Any thing different than this means the band switch system/assembly is "out of sync"!

The band switch "will" rotate "continuously 360 degrees" in either direction! There are "NO" stops to the band switch!

You will need a "metric" hex tool, size "1.5mm". Do NOT attempt to remove/loosen the coupler set screws with any tool but a 1.5mm hex tool. If you do you will permanently damage the set screws.

Do NOT loosen the plastic couplers' front set screws on the long band switch shaft unless you are replacing a broken coupler!! If the coupler is NOT cracked or broken and you have found S22 is out of sync with the rest of the band switch system/assembly, then the only set screws you need to loosen are the 2 "rear" set screws.

Do NOT over tighten the set screws! Over tighten set screws will "break" or cause the coupler to "crack" at the set screws! If this occurs you will have to replace the coupler! You do NOT have to replace the coupler simply because it's old. As the old saying goes, "if it ain't broke don't fix it!!!".

The end result, when this alignment is done properly, the front panel band switch knob pointing exactly at 10 with results in S22's shaft flat spots be exactly vertical on the right side and exactly horizontal on the bottom. Any other S22 shaft flat spot alignment with the band switch knob pointing to exactly 10 on the front panel will be wrong!

Ceramic disc capacitors "typically" do not fail nor do they change values over time. That does not mean ceramic disc capacitors NEVER fail.

There are times when disc capacitors do fail such as pulling hard/abusing the leads that can lead to the internal capacitor plates to separate from the leads. Capacitors that are subjected to a voltage that exceeds the safe working voltage of the capacitor can be physically damaged, they explode.

C12, the 100pf ceramic disc capacitor, has a voltage rating of "500VDC". This capacitor is listed in the 530 parts list on page 21 under "TS-530 General" listing.

C25, the capacitor across the relay coil terminals, should be at least 25VDC. When coil voltage is removed, switching from transmit to receive, the magnetic field that surrounds the coil collapses. As the magnetic field collapses, the magnetic lines cut the windings of the relay coil, resulting in an "induced" voltage that can be much higher than the 12VDC source voltage. Diode D10 on the AF unit provides some protection against this collapsing magnetic field induced voltage.

Again, unless there is physical damage and/or the capacitors' working voltage has been exceeded causing destruction of the capacitor, most ceramic disc capacitors do not fail over time.

You bought a "recap kit" of electrolytic capacitors. I assume you bought the kit to replace electrolytic capacitors.

What evidence or troubleshooting results do you have that says you should replace electrolytic capacitors?

Are you replacing the capacitors simply because they are old? If so then don't! Unless there is evidence whether physical damage to the capacitor or evidence through troubleshooting that indicates one or more of the electrolytic capacitors are failing, don't simply replace them because they are "old"!

It was simply included in the deal. The caps on the relay board are the only ones I'm looking at right now.

I disagree. Any electrolytic older than 15 or so years old should be considered suspect and an accident waiting to happen. Especially if the device has been sitting around a few years. These caps may show no external evidence of crystalizing.

The subject of "pre-emptive" replacement of electrolytic capacitors has been the subject of debate on this forum and others. Aluminum electrolytics that are in installed/operating equipment are constantly being "reformed" when powered on and off. Measurement of Capacitance, DC Leakage Current (DCL), and ESR confirms this. If you have a rig that hasnt been powered on in 5 plus years then "soft starting" with a variac or an in series light bulb is probably warranted. One of the risks involved with pre-emptive cap change out is the lifting of circuit board foils. With a 30+ year old rig how often would you wholesale change out the caps? On a 15 year cycle? When you buy an "NOS" capacitor kit off ebay you do not know where these caps are relative to shelf life. Do you reform these caps before installing them? Also, with the new downsized components I am still on the fence when it comes to reliability. They pack an awful lot of ufds in a very small can.

I suggest a better approach would be to purchase or build an inexpensive ESR test set. These testers can test the capacitor in circuit. Capacitors at or near end of life can still have capacitance values within the nameplate +/- tolerances. Therefore an LCR meter isnt the best test. DC leakage current and ESR are better tests. Hams who repair and service rigs depend on test equipment and using an ESR meter to test suspect and/or key electrolytics (power supply filter caps?) would be more in line with how an electronic technician would operate. Just my 2 cents. Terry K9TW

Topic: 30386 Message: 30386

Hi Friends,

My TS 520SE's out put power is low.It gives 50W on 14 MHz,around 35 W on 7,3.6 & 1.8 and even low on 21,28 Mhz.when I measured with Comet CMX-1 power meter.

This question would have answered many times before but I've discovered this low power only recently as I did not had a meter to check earlier.

Does it needs re-alignment?
Are the finals reached to it's end of life?
Is the drive power is low? (will it be ok if I plug a new 12BY7A and see)

Grateful for any suggestions

Hi Ravi.
It could be all the issues u suggested i would check to see how much rf drive is coming out of the 12by7 driver tube also check to see what level of signal rf is coming into 12by7 if u have plenty coming into 12by7 then faulut lies elsewhwre see what's coming out of 12by7 should be lots maore than coming in go to grids of 6146's make sure u dont touch the ht see what u have there.if all okay check voltages on the screens and on anodes of 6146's be careful.
If all okay as per manual do u have service manual if not email me vk2oz@... i will give info u need to do this we will leave it at that fer now Ravi hope this helps u i have a ts520se aas well gud rig simple to fix.

Hello Ravi,

Your problem could be caused by alignment, especially since power output is not consistent on all bands. Since power output is not consistent on all bands I do not believe your problem is caused by bad tubes. Tubes will not cause the power output differences you are experiencing on different bands.

Check the PC board and ground mounting screws to ensure the mounting screws are tight.

You might clean the band switch and Mode switch wafers with contact cleaner first. Use only enough cleaner to do the job then use canned air to remove any/all cleaner residue.

If cleaning the band switch and Mode switch wafers does not fix your power output problem then I recommend performing the COIL PACK alignment.

You can download the complete TS-520S service manual which contains the COIL PACK alignment at Gordon's website

www.n6wk.com/kenwood/

Gordon's TS-520SE service manual does not contain the alignment section but his TS-520S service manual does. The TS-520S COIL PACK alignment is the same for the TS-520SE. Therefore, you can use the TS-520S service manuals' COIL PACK alignment steps for your TS-520SE.

Thanks Mike (w5rkl) and vk2oz for your suggestions.
Yes I have the service manual.Finals could have been replaced by the previous owner but no records with me They are S2001A's.
When I got this rig about 3 years ago,mike (w5rkl) suggested to clean band and mode switches,which I did.
I have not done an alignment coz she is ok with TX/RX until recently I've observed this low out put.That;s why I thought that she needs re-alignment.

All good points. There are certain electrolytic caps that I would swap without hesitation. Such as power supply caps. If these aren't formed properly, are leaking, not to spec, or crystalized, then a failure of these caps can do a lot of damage as opposed the the standard bypass/circuit electrolytic caps that just leak out onto the circuit board.

Ok, back at it! I've cleaned the connectors on all boards. Checked R15, which I recently replaced. All seems good. Voltages on drive tube are within specs and switching when put into transmit. Seems like there is no drive going to the finals. Idle current at 60ma.

Thanks
Steve

Meter switch to ip mode, only reading 60ma idle current. No RF. I know that when I used to hit send, the meter would "bounce up" a bit and return to nil. Now it doesn't do that anymore. I also notice that the receive is acting funny. The marker signal is very weak and sometimes isn't there at all. I remember once the other day when tuning in the marker signal, that it faded out to barely audible with the volume all the way up. The cw sidetone is plenty loud. It's as if there isn't anything there for the finals to work with signal wise.

Kurt --I agree visual inspection is part of any refurb/repair and if it reveals ruptured seals, leaking electrolyte, swelled cans etc. then of course change them out. I was just talking about wholesale change out of all electrolytics when you buy a used rig or on some periodicity as a means to pre-empt failure. If one of the main power supply caps fails of course change out both, but would you recommend changing them out on some interval just as a precaution even if loaded Plate Voltage is within spec? I guess you could do that as they are relatively easy to change out. I would not do it. Terry

Hi Alan
ZL4FM,

I am in Birkenhead, North Shore,Auckland

Jeff
VK4FNRS...re better antenna

I'm on to it. I am heading out to get some more wire today and have downloaded some info from the net (DXZone and others). I think I now have enough info to attempt my first antenna...another milestone perhaps?

I tried again last night using the procedures suggested by Terry (K9TW). All went well except that I had to turn the RF Gain to around the 6 mark to get the calibration to S9...any lower and it went right off the dial. Eventually I conceded defeat and have decided that, until I have a half way decent antenna I will be chasing my tail. Problem is I don't have the time in the evening after work to sort anything so it has to wait until weekends.

One thing I have noticed is that the Main Tuning dial(s) on the 530S seem to be binding on each other to the extent that they both turn at the same rate. Obviously the rig needs some TLC as it is no where near as pristine as the 520S. I think I might try the 520S over the weekend if I can sort the antenna first

Gentlemen,
I have a 530s and the RF gain should always be fully clockwise when listening. S. meter is correct in this mode. turn it back if a station is close and overloading the front end.

Hi Alan

Your remarks are confusing me, concerning the RF gain and the "calibration". Are you expecting the S-meter to hover at some pre-determined value ? You know, don't you that you turn the RF gain all the way clockwise, and the S-meter should rise and fall with the strength of the signals coming in.

If you turn it counter-clockwise, the S-meter probably will go up scale (that is the way most radios work, anyway) and the signals will get weaker and weaker, because you are forcing your radio to act as if a very strong signal is coming in, when in fact there is nothing much there!

Also, remember that these types of radios are meant to work with a 50 ohm antenna. That means, a resonant dipole working through 50 ohm coax cable, such as RG 8 or 58. If you are trying to feed it with a random piece of wire, it is no wonder that you are not getting much performance out of the receiver.

If you insist on using a random piece of wire, please get an "antenna tuner" which will match the impedance of the random wire (probably very high) to the radio (50 ohms, as stated)

Please clarify if that is how you are trying to operate the rig.

73, Jim AG3Y

Hi,

Have you approached your local Ham club?

I am in Dunedin,
The first HF set I ever used was a 530S and we have one at our local club in the shack. So I am really familiar with it.

If you have any questions you can email me of the list if you want

alan@...

save annoying everyone else.

Best of luck getting you license.

Alan

To start just use a long wire for receiving. It can be an open wire all the way from the xcvr to a tree outside somewhere.

I use #18 insulated stranded wire for this kind of antenna.

If you cannot receive with this kind of antenna a more complex antenna may not do you any good.

Random long wires do work fine for receiving. They do not work for transmitting.

A good transmitting antenna needs to be resonant at all transmitting frequencies. This makes for multiple antennas or complex antennas.

Using a tuner with a real long wire will only give you marginal gains. Probably not worth the effort or expense.

Jeff
VK4FNRS...re better antenna

I'm on to it. I am heading out to get some more wire today and have downloaded some info from the net (DXZone and others). I think I now have enough info to attempt my first antenna...another milestone perhaps?

I tried again last night using the procedures suggested by Terry (K9TW). All went well except that I had to turn the RF Gain to around the 6 mark to get the calibration to S9...any lower and it went right off the dial. Eventually I conceded defeat and have decided that, until I have a half way decent antenna I will be chasing my tail. Problem is I don't have the time in the evening after work to sort anything so it has to wait until weekends.

One thing I have noticed is that the Main Tuning dial(s) on the 530S seem to be binding on each other to the extent that they both turn at the same rate. Obviously the rig needs some TLC as it is no where near as pristine as the 520S. I think I might try the 520S over the weekend if I can sort the antenna first

On those recievers it is normal tor the S-meter to respond that way.
 You normally run the RF gain at max, this setting , along with the AVC circuit allows weak signals to be heard and strong ones will reduce the IF gain and have a reasonable volume . Using the AF gain to control the overall volume is recommended.
Kenwood fan here.

I know this is a Yahoo list devoted to the Kenwood models 520, 530,820 but, I just have to ask one simple question. I may take delivery in a few days of a TS-440S HF rig, I have heard that there is a electronic issue with the display. It looses the normal frequency digital readout and reverts to a bunch of dots.

I was told there is either a mod to fix this problem or a parts kit [with instructions] to fix the problem. Anyone on the list aware of this and can steer me in the right direction, without me having to look for and join a TS-440S specialized Yahoo group?

30407. Re: [TS-520_820_530_830] zero beat

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-03-25 03:35:28 UTC
From: Jim S
Topic: 30404 Message: 30407

If the crystal calibrator is a 100 Khz one, you should hear a tone every 100Khz up and down the band. If you are listening in SSB, the tone should go from a rather high pitch to a very low one, and then disappear. Depending on how much rejection of the other sideband your radio is capable of, you may hear the tone coming back up in pitch but at a very low volume, if you continue to rotate the dial in the same direction. Zero beat is that frequency below which the speaker cannot produce the tone. Actually with today's radios, almost anything below 300 hz is considered "zero beat".

If you were to zero beat the crystal calibrator with WWV, for instance, by tuning the trimmer cap across the crystal, you would hear a tone created by the calibrator frequency beating against WWV's carrier, and as you "tweak" the crystal's frequency, you should hear that tone get lower and lower, finally causing a pulsing of the carrier as the calibrator "beats" with it. If the levels are closely matched, you can actually watch the S meter pulse up and down, and the two carriers alternately reinforce and cancel one another out.

This is true zero beat.

Hope this helps. 73, Jim AG3Y

Hi

Sorry if this subject has been hammered on before but...

I will be changing my 33 year old finals this weekend. It will be my first time. i have access to a scope but not an RF probe. I was thinking about looping a bit of coax to make a sniffer Antenna for the probe and seeing if i get a signal to neutralize that way. is this a good idea? Any other suggestions? I also will be able to bet another Kenwood to receive the 28 mhz signal and then tune for a dip. would this be better?

Thanks

steve

'Morning Bob:
I just signed up on that website and awaiting approval for membership. I have at the moment three articles of technical information [from another source] on the issue with the TS-440S display. It appears that the problem stems from part of the PLL circuit and some kind of "glue" that was applied to a specific circuit during manufacturing of the radio.

This glue supposedly was installed to prevent vibration when the rig was operated in the mobile. However the one article states that over time the glue becomes electrically conductive and causes these strange dots in the digital display. Once I join the TS-440 Yahoo group I can then query other members to see what is the best approach to solving the problem.

The radio should be delivered sometime next week and the owner made me aware of the intermittent problem, which BTW only seems to happen randomly and not on every frequency or band. Nonetheless, thanks for your input on this.

Sometime in June the wife and I will be in your neck of the woods. Our daughter recently got tenured as an Associate Professor and teaches at a local college there in the Seattle area.

Hello Steve,

The key is to adjust the neutralizing variable capacitor for the lowest indication on the RF Probe, scope, or separate receiver. If you follow the steps in the 520 manual you will do fine.

Just remember to set the rear panel SG switch to ON when the neutralizing adjustment is completed. If you forget this step you could easily think you did something wrong that broke your transmitter.

KD0ILM:

Thanks for asking the question! I'm new to HF, Tubes and all this stuff too. Zero beat is something I didn't really understand until I started spinning knobs on my tech special TS-820s.

If you go spinnin' round the dial, you'll hear these squealing tones that drop in frequency if you spin the tuner the right direction. Right at the end of where you can hear the tone, you'll start hearing voices! Bam. Zero beat. You are now matching the frequency of the transmission.

KD0FDS
(total newbie)

Steve;
I use a 10X probe on a 100MHz Tektronix scope with no problem right off the coaxial cable to the dummy load.
I connect a pin to the coaxial "T" pin and the scope probe ground to the outer shell of the "T" and take
the reading. If you set this up as per the manual, you should not have a problem - Remember that the
"SG" switch is off during this process.

Regards

Chuck, KJ4GU

Hi,

I have used a short length of coax directly from my transmitter antenna connector to the scope input. MAKE SURE THE FINALS ARE DISABLED FIRST!!! Do the adjustment for minimum output. On mine I can get to zero on the scopes most sensitive setting. After you are done, don't forget to turn the finals back on - the "sg" switch on yours.

I was thinking about looping a bit of coax to make a sniffer Antenna for the probe and seeing if i get a signal to neutralize that way. is this a good idea? Any other suggestions? I also will be able to bet another Kenwood to receive the 28 mhz signal and then tune for a dip. would this be better?

Hi chuck,

that was another way I thinging of going. I will be borrowing this scope and had concerns about blowing it up. I guss as long as the SG switch is off, I will have no problem with a 20X probe. I also have a 1X probe, but I I dont know what the freq response is on it. with any luck I will be going from 50 watts back to 100 after this is done

steve

Sound advice Chuck!

The manuals show a lot of test equipment, some appear to be quite sophisticated. However, you don't need to spend a lot of money on test equipment just to satisfy the pictorial setups shown in the manual. Remember, the service manuals were written based on test equipment readily available at factory service departments. The average ham doesn't have all that test equipment.

Using common sense and simple test gear you can achieve the same results. You can build a simple RF probe using a blocking capacitor and a couple of diodes. An RF probe is not a sophisticated piece of test gear. It only "appears" to be. The following link will show you how simple an RF probe really is.

You can find used vacuum tube VTVMs on eBay. It doesn't matter which one you choose, vacuum tube or all solid state, they all do the same thing!

There isn't much to a vacuum tube VTVM, typically 2 tubes, a dual Triode such as a 12AU7 and a dual diode 6AL5, tubes that are readily available and "cheap". Most of the time the original tubes are still working rather well. Triode tubes such as 12AU7s and diode tubes such as 6AL5s don't fail, they keep on working even after 40 years. In most cases you do not have to replace them, just align the VTVM using the simple instructions in the VTVM's manual. I have 2 vacuum tube VTVMs, one from Knightkit and the other from Eico and both have all the original components except for the old dried up half wave rectifier filter capacitor (typically only one cap to worry about).

Remember, this is "Amateur Radio" not "NASA Rocket Science". Therefore, you don't need expensive sophisticated test equipment to troubleshoot and repair ham gear. Many problems can be found rather quickly by simply taking voltage readings. Voltage readings can tell you a lot how a circuit is performing.

I built a simple RF probe inside a short piece of small diameter PVC pipe and a heavy piece of wire through a PVC pipe cap, a .01ufd 100VDC disc capacitor and a couple of 1N5711 diodes in series (I have quite a few 1N5711 diodes so I used them) plus a short piece of RG-174 coax cable. As you can see, you don't need to spend a lot of money for a simple VTVM and an RF probe.

One more thing. The link I provided shows a resistor, 4.7Meg, in series to the VTVM. A much lower resistance will work, 2K or so will do fine. You want a much RF signal present at the input to the VTVM as possible.

NEVER attempt to measure the RF signal at the output of the final amplifier!! The signal level at that point will destroy the RF probe and could easily damage your VTVM.

I agree with the other response, made sure the "SG" switch is set to "OFF" when making the neutralization adjustment but also don't forget to set the SG switch back to ON when you have finished neutralizing the final amplifier.

Safety note:
Use an insulated shaft screwdriver when adjusting the neutralizing cap, as full HT will be present in the PA compartment. If you don't have one, wind several layers of insulating tape around the shaft leaving just the tip exposed.

A short to the case here would be exciting but possibly expensive.

I have tried to use a second radio to monitor leakage, but found the RF leakage altered so much as I touched the cap that I found the method useless.

I now use a 'scope connected directly to the antenna socket with a low wattage 12 volt lamp connected across it to present a low resistance load for any leakage present. I suppose a 47R load would be ideal.

The 4.7M resistor in the RF probe converts the peak reading of the probe to RMS displayed by the meter.

Selling the following for a fellow Ham. Lincolnwood, Illinois.
Contact me for details!

sberger@...

Kenwood TS-830S HF Transceiver

This top-of-the-line 100w. rig works like new and has been pampered. All functions work well and includes extra CW filter for clear CW operations. Features 1.5 ☐ 30 MHz bands with lighted meter, digital frequency display, VOX, Speech Proc. etc. Exceptionally clean inside and out. Includes original manual. Will pack carefully at my cost. Shipping at your cost. Buy Now for $350 or best offer.

DSP Audio noise reduction Module
Hear-It DSP Module (under GAP name) cut down static and pulls out those weak stations you couldn't hear before. Sits between rig and external speaker for DSP noise reduction features only found in newer rigs. What a difference it makes! Buy now for only $125 or best offer.

LogicKit CMOS-4 Keyer
Plug in your paddles and away you go with superb CW keying. Adjustable weighting, keying speed and many other features. Even includes 4 memories for recorded messages such as CQ, etc. Great for contesting. Press a button and each message is sent automatically. Buy now for only $50 or best offer.

The dots indicate the PLL is "out of lock" usually because of this aging potting compound.
My TS440s has not quite gotten that far but above the 20 M band I have a terrible chirp on transmit due to this potting compound failure.

Subject: [TS-520_820_530_830] Re: Repair Kit: TS-440S

'Morning Bob:
I just signed up on that website and awaiting approval for membership. I have at the moment three articles of technical information [from another source] on the issue with the TS-440S display. It appears that the problem stems from part of the PLL circuit and some kind of "glue" that was applied to a specific circuit during manufacturing of the radio.

This glue supposedly was installed to prevent vibration when the rig was operated in the mobile. However the one article states that over time the glue becomes electrically conductive and causes these strange dots in the digital display. Once I join the TS-440 Yahoo group I can then query other members to see what is the best approach to solving the problem.

The radio should be delivered sometime next week and the owner made me aware of the intermittent problem, which BTW only seems to happen randomly and not on every frequency or band. Nonetheless, thanks for your input on this.

Sometime in June the wife and I will be in your neck of the woods. Our daughter recently got tenured as an Associate Professor and teaches at a local college there in the Seattle area.

Doug W7FDF

I seem to having a problem now with my ALC not coming up on 10 meters. I had to crank up the car more than normal for it to show. I am about to change the driver tube to see if that cures that problem. I am seeing little on the scope, I have the watt meter in line, then the dummy then a some coax (about 2 feet) should i reove the meter and the 2 foot coax to the probe?

Thanks

steve

UPDATE: I changed the drive and the ALC was working on 10 meters. i got rid of the length of coax and i could see the signal on the scope FB I was able to tune down to min. i buttoned up the radio and i am putting out close to 100 watts...BUT I also relaozed i was not at 28.5 MHZ when i neutralized..it was more like 28.2 MHZ. Is that important? Should i redo it?

pictorial setups shown in the manual. Remember, the service manuals were written based on test equipment readily available at factory service departments. The average ham doesn't have all that test equipment.
> >
> > Using common sense and simple test gear you can achieve the same results. You can build a simple RF probe using a blocking capacitor and a couple of diodes. An RF probe is not a sophisticated piece of test gear. It only "appears" to be. The following link will show you how simple an RF probe really is.
> >
> > You can find used vacuum tube VTVMs on eBay. It doesn't matter which one you choose, vacuum tube or all solid state, they all do the same thing!
> >
> > There isn't much to a vacuum tube VTVM, typically 2 tubes, a dual Triode such as a 12AU7 and a dual diode 6AL5, tubes that are readily available and "cheap". Most of the time the original tubes are still working rather well. Triode tubes such as 12AU7s and diode tubes such as 6AL5s don't fail, they keep on working even after 40 years. In most cases you do not have to replace them, just align the VTVM using the simple instructions in the VTVM's manual. I have 2 vacuum tube VTVMs, one from Knightkit and the other from Eico and both have all the original components except for the old dried up half wave rectifier filter capacitor (typically only one cap to worry about).
> >
> > Remember, this is "Amateur Radio" not "NASA Rocket Science". Therefore, you don't need expensive sophisticated test equipment to troubleshoot and repair ham gear. Many problems can be found rather quickly by simply taking voltage readings. Voltage readings can tell you a lot how a circuit is performing.

I recall the manual giving 14 MHz as the frequency to do the neutralization
procedure on. Not 10M !
I never got much ALC reading on 10M, even when my TS520 was new.

Topic: 30408 Message: 30430

For the newer folks who are interested in understanding why and what we are doing when we neutralize an RF amplifier, Tom W8JI has a really good "white paper" on neutralizing RF amplifiers. His section on neutralizing Grid Driven Tetrodes is very interesting and an easy read. It amazes me that almost every thing we do with these Hybrids goes back to basic fundamental electronic theory. In this case understanding what a capacitor is and the internal construction of a vacuum tube is where this understanding starts.

I have always neutralized (any rig with pair of 6146 finals) around 21.5 just because the null is typically easier to see and then I move up to around 28.5 to fine tune. Probably an extra step that is not necessary. Maybe one of those "Truths and Myths" ? For the newer folks just be careful and use insulated tuning tool. Lots of fire works possible here and dont want anyone to get hurt. Terry K9TW

Yep, I agree 100%! Without the basic knowledge, troubleshooting and repair becomes a "guessing game".

As I dig into this..I find now that the CAl signal is at s7 to 9 on 40 and 80, but goes down as i go up in freq. at 28.5 mhz it is down to about 4, what is this telling me?

I guess all is good with neutralization so far. i manage to get a quick report from russia during today concert and a better report from a local. 100 watts now with a dipole.

I always do my rig final neutralizations on 10 meters. If you do it on 20
or 15 meters, there's no guarantee that the final tank circuitry will be
"clean" on 10 meters.

Topic: 30436 Message: 30436

Ron,
Just got and old 820s with cw filter. Did your mod from 2007.
Worked like a charm.
Thanks!!!
Frank aa4ex franktaylor13@...

30437. TS 520SE lack of drive in the tune position 10m and 15m

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-03-26 18:55:45 UTC
From: k4ynd
Topic: 30437 Message: 30437

I have had a TS 520SE for over a year now has always worked great on 80,40,20 and 15.. When I got it. I could not get any drive on 10 meters (in the tune position.) Today I tried to tune up on a dummy load on 15 in the tune position. When I try to adjust the drive knob the needle (ALC position) barely shows anything.

Im hoping this points to a very soft drive tube (still tunes on 40)

What do you think

30438. TS520S - RF spike on LSB TX

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-03-27 01:00:09 UTC

Topic: 28156 Message: 30438

Hi All,

I have a TS520S that give a burst of RF when I switch to TX on LSB. It is band independent, doesn't matter if it's hot or cold, doesn't happen on USB. Also happens with no mic connected using the send switch. On air reports are great, no one can hear anything but I know it's there and I don't like it.

Tubes are neutralized, I've run an alignment and found nothing unusual, AVR volts are good, supply volts on the carrier board 8.3V and crystal switching looks ok.

Has anyone come across this or have an idea where to start?

It does not do it on USB because the carrier is fully balanced on USB. You cannot fully null the carrier for both USB and LSB. You will find that if you set the null on LSB then USB will be off.

You are supposed to set the null so you have the same amount of leakage on both USB and LSB. It will take you some FIDDLING to figure out how to get the best balance.

My 530SP is the same way. For 10 M I have to tune in the CW position. It took me the longest time to figure it out, but sometimes when I put the band switch at that indent it does not make good contact. I have learned that when 10M just won't tune, wiggle the band selector switch just a little and watch the needles jump (still in CW).

Thanks Bob,

I paid particular attention to the Balanced Modulator adjustment as it makes sense that it would come from there if anywhere. I couldn't get a complete null on LSB and trying to balance between the LSB & USB I couldn't find a setting for VR1 and TC1 that would give me equally low leakage for both and found LSB particularly touchy to adjust. Since I work the low bands only with this rig I opted in favour of minimum carrier leakage on LSB. That gave me less than a milliwatt of leakage on LSB and less than I could measure on USB. I think that's more than good enough.

However the burst or spike remains on LSB TX. As soon as I go to TX I get a spike of maybe 250mS or less and on a peak reading watt meter it shows about 20W PEP. After that the radio can stay in SSB TX and the power meter reads zero. I can see this spike on several different power meters but listening on a comms receiver I can't hear it on frequency which explains why I haven't had bad reports on air.

Mine does the same exact thing. I need to find the time to really check it out. I believe it is a spike getting in the modulator and momentarily unbalancing it.

What position is the meter switch set to when this happens? Do you see the ALC meter setting "jump" when you switch from receive to transmit? Do you actually see RF output on an external watt meter when this occurs?

Hi Mike,

This radio has been unused for the last year or so while I
concentrated on microwave field operation and when I fired it up
yesterday I wasn't sure if I was seeing things and couldn't remember
if this was normal - I hope it isn't. Bob confirms he sees a similar
thing on his radio. I forgot to mention that I can also see a surge
in tube current at the same time. It's hard to get exact readings
with something that occurs so quickly but I'm convinced there's RF there.

There is RF there . It shows on the SWR/PWR meter.

Mine is new to me and I have not made an effort to find the problem yet.

Hello Bob and Lou,

Lou, this problem didn't occur when you shut the 530 down for a couple of years.

I'm not sure the problem is a carrier null/balance adjustment between USB and LSB. The problem could be caused by RL1 relay on the IF board.

I wouldn't rule out the relay RL1 on the IF Unit.

The problem could be caused by a spike generated by RL1 relay terminals that control "RLR" and "RLT" on the AF Unit. These relay terminals switch 9VDC between "RLR" and "RLT". Note on the schematic that the 9VDC these relay terminals switch also powers the speech amplifier and associated support circuits such as Q15, Q16, and Q17. A spike on the 9VDC can result in a momentarily unbalance condition in the BM.

Hi Mike,

I follow your reasoning re a spike on the 9V rail causing problems
including an unbalance in the BM but I wonder why it would only occur
on LSB? It's late Sunday here and with me back at work tomorrow I
won't get a chance to look at the radio for a few days but I will follow up.

Evening Lou,

I guess I should have said I'm not sure the carrier null adjustment is the sole source of the problem. It's quite possible that the carrier null adjustment and the relay on the IF unit are both contributing to the problem.

That relay, same relay on the AF board in the 830 and the IF and Filter boards in the TS-120 and TS-130, has a history of causing quite a few problems.

30450. Re: [TS-520_820_530_830] TS 520SE lack of drive in the tune position 10m and 15m

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-03-27 13:11:40 UTC
From: John Davidson
Topic: 30437 Message: 30450

New out of the box, My TS520 had a slight bump on the ALC meter when peaking the drive capacitor in TUNE on 10M. The lower bands were always high on the meter when tuning.
Now the same 520 has to be drive tuned for a peak of plate current and then the plate tuning dipped, ONLY ON 10m. (On my 2nd set of 6146 tubes the last 20 years)I have never seen more than 70 W out on 10M. I have never tried to tune for more than 200 mA. The lower bands always gave me 100 Watts out.

Subject: [TS-520_820_530_830] TS 520SE lack of drive in the tune position 10m and 15m

I have had a TS 520SE for over a year now has always worked great on 80,40,20 and 15.. When I got it. I could not get any drive on 10 meters (in the tune position.) Today I tried to tune up on a dummy load on 15 in the tune position. When I try to adjust the drive knob the needle (ALC position) barely shows anything.

Im hoping this points to a very soft drive tube (still tunes on 40)

What do you think

K4YND

0h well, it has been about 7 years since I had to do any repair work on the old
TS520 workhorse and read thru the book.
I had a relay driver transistor fail.

30452. Re: [TS-520_820_530_830] Re: TS520S - RF spike on LSB TX

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-03-27 13:32:55 UTC
From: Bob Macklin
Topic: 28156 Message: 30452

This is what I believe the problem probably is.

The person I bought my TS-520 from was trying to fix it with the carrier null. But the problem only occurs when the relay activates.

Thanks for telling me where to look.

Hello Bob and Lou,

Lou, this problem didn't occur when you shut the 530 down for a couple of years.

I'm not sure the problem is a carrier null/balance adjustment between USB and LSB. The problem could be caused by RL1 relay on the IF board.

I wouldn't rule out the relay RL1 on the IF Unit.

The problem could be caused by a spike generated by RL1 relay terminals that control "RLR" and "RLT" on the AF Unit. These relay terminals switch 9VDC between "RLR" and "RLT". Note on the schematic that the 9VDC these relay terminals switch also powers the speech amplifier and associated support circuits such as Q15, Q16, and Q17. A spike on the 9VDC can result in a momentarily unbalance condition in the BM.

Neutralizing on 28.2 verses 28.5 is not a problem so don't worry about that.

This is similar to how the transceiver can switch momentarily from receive to transmit if the VOX switch is set to ON when changing modes (moving the Mode switch from CW, USB, or LSB).

A voltage spike is created when switching the mode switch with VOX turned ON. The spike creates noise that appears at the input to the VOX Unit. The noise causes the VOX Relay amplifier to momentarily conduct energizing the relays which causes the transceiver to switch from receive to transmit then back to receive.

30455. A MILESTONE FOR ME WITH TS-530S

Hi Jim,

I'm glad I am not the only one confused:-)

Just to clarify - I am ONLY using the rig to receive as I am not yet licenced. I believe from information given here and elsewhere that a random length of wire is OK to receive(but not for tx) but I am in the process of making up my first Dipole. Poor weather put that on hold this weekend! Also we live in a dip and the reception for cellphones is marginal so I assume that the reception for a random wire antenna probably leaves a lot to be desired.

I assumed the S meter would fluctuate with the signal but also thought that it needed to be around the S9 mark and that when it shot off the dial I should tune it back. The problem I have is that although the manual covers each dial and button it does not explain in words I can understand what the actual effect is or why it is used. I intend to try and get someone at the local Ham Club to help me here - and also maybe run the rig in their shack so that I can be sure that it is operating correctly as it appears to have had a less than sympathetic life - unlike the 520S that I have but have not used yet.

As long as members here can put up with my basic questions I am actually learning something and at least my interest is being maintained.

Subject: Re: [TS-520_820_530_830] Re: A MILESTONE FOR ME WITH TS-530S

Your remarks are confusing me, concerning the RF gain and the "calibration". Are you expecting the S-meter to hover at some pre-determined value ? You know, don't you that you turn the RF gain all the way clockwise, and the S-meter should rise and fall with the strength of the signals coming in.

If you turn it counter-clockwise, the S-meter probably will go up scale (that is the way most radios work, anyway) and the signals will get weaker and weaker, because you are forcing your radio to act as if a very strong signal is coming in, when in fact there is nothing much there!

Also, remember that these types of radios are meant to work with a 50 ohm antenna. That means, a resonant dipole working through 50 ohm coax cable, such as RG 8 or 58. If you are trying to feed it with a random piece of wire, it is no wonder that you are not getting much performance out of the receiver.

If you insist on using a random piece of wire, please get an "antenna tuner" which will match the impedance of the random wire (probably very high) to the radio (50 ohms, as

stated)

Please clarify if that is how you are trying to operate the rig.

First about the S-Meter. It shows the signal and noise. Disconnect the antenna and it should be very low. and the noise in the speaker should be very low. Reconnect the antenna and the noise should increase as well as the reading on the S-Meter.

Good received signals will show on the S-Meter above the noise level. But for SSB they will be bouncy.

On very strong signals turn down (CCW) the RF Gain control. But when you do this the S-Meter will move CW.

Allan,
 You do not have to TURN the S Meter down!!!!
This meter in receive only shows the strength of the incoming signal.

FOR TRANSMIT YOU MUST TUNE THE SET TO THE BAND!!!!!

When TUNNING The SET for TRANSMIT, you do the following:
1. set the BIAS for 60MA (once this is set , this step does not have to be repeated on each tune up)
BIAS CONTROL is in the access panel on the left hand side of the set.
2 METER SWITCH to ALC & MODE switch to TUN, ADJUST the DRIVE to give MAX DEFLECTION on METER.
3, MODE SWITCH to IP ADJUST PLATE CONTROL to DIP /LOWEST reading on METER
4. MODE SWITCH to CW ,METER SWITCH TO RF & ADJUST PLATE & LOAD CONTROLS to MAX DEFLECTION on METER

This is a quick tune -up for the set & must be done each time you change BAND , This also tunes the set for best rec in each BAND.

TUNNING should be done into a DUMMY LOAD of at least 50watts, If you don't have one , buy or build one they are not expensive to build.

Jeff

Folks--The S-meter business is my fault. I was trying to tell him how to maximize the receiver front end sensitivity by ensuring that the driver control was peaked. I was trying to explain to him how to do that using the Xtal Calibrator. That is where he is coming up with the S9 business. I didnt want him tuning into a dummy load when he was having trouble understanding the operating manual instructions for receiver operation. You cant hurt anything peaking the driver control in receive mode. Apparently communication and teaching is not my strong suit. I will butt out at this time. He truly needs a local ham to demo for him. Terry K9TW

Subject: Re: [TS-520_820_530_830] A MILESTONE FOR ME WITH TS-530S

Allan,
You do not have to TURN the S Meter down!!!!
This meter in receive only shows the strength of the incoming signal.

FOR TRANSMIT YOU MUST TUNE THE SET TO THE BAND!!!!!

When TUNNING The SET for TRANSMIT, you do the following:
1. set the BIAS for 60MA (once this is set , this step does not have to be repeated on each tune up)
BIAS CONTROL is in the access panel on the left hand side of the set.
2 METER SWITCH to ALC & MODE switch to TUN, ADJUST the DRIVE to give MAX DEFLECTION on METER.
3, MODE SWITCH to IP ADJUST PLATE CONTROL to DIP /LOWEST reading on METER
4. MODE SWITCH to CW ,METER SWITCH TO RF & ADJUST PLATE & LOAD CONTROLS to MAX DEFLECTION on METER

This is a quick tune -up for the set & must be done each time you change BAND , This also tunes the set for best rec in each BAND.

TUNNING should be done into a DUMMY LOAD of at least 50watts, If you don't have one , buy or build one they are not expensive to build.

First about the S-Meter. It shows the signal and noise. Disconnect the antenna and it should be very low. and the noise in the speaker should be very low. Reconnect the antenna and the noise should increase as well as the reading on the S-Meter.

Good received signals will show on the S-Meter above the noise level. But for SSB they will be bouncy.

On very strong signals turn down (CCW) the RF Gain control. But when you do this

the S-Meter will move CW.

Subject: [TS-520_820_530_830] A MILESTONE FOR ME WITH TS-530S

Hi Jim,

I'm glad I am not the only one confused:-)

Just to clarify - I am ONLY using the rig to receive as I am not yet licenced.

I believe from information given here and elsewhere that a random length of wire

is OK to receive(but not for tx) but I am in the process of making up my first Dipole. Poor weather put that on hold this weekend! Also we live in a dip and the reception for cellphones is marginal so I assume that the reception for a random wire antenna probably leaves a lot to be desired.

I assumed the S meter would fluctuate with the signal but also thought that it

needed to be around the S9 mark and that when it shot off the dial I should tune

it back. The problem I have is that although the manual covers each dial and button it does not explain in words I can understand what the actual effect is or why it is used. I intend to try and get someone at the local Ham Club to help

me here - and also maybe run the rig in their shack so that I can be sure that it is operating correctly as it appears to have had a less than sympathetic life

- unlike the 520S that I have but have not used yet.

As long as members here can put up with my basic questions I am actually learning something and at least my interest is being maintained.

Subject: Re: [TS-520_820_530_830] Re: A MILESTONE FOR ME WITH TS-530S

Your remarks are confusing me, concerning the RF gain and the "calibration". Are you expecting the S-meter to hover at some pre-determined value ? You know, don't you that you turn the RF gain all the way clockwise, and the S-meter should rise and fall with the strength of the signals coming in.

If you turn it counter-clockwise, the S-meter probably will go up scale (that

is the way most radios work, anyway) and the signals will get weaker and weaker, because you are forcing your radio to act as if a very strong signal is coming in, when in fact there is nothing much there!

Also, remember that these types of radios are meant to work with a 50 ohm antenna. That means, a resonant dipole working through 50 ohm coax cable, such as RG 8 or 58. If you are trying to feed it with a random piece of wire, it is no wonder that you are not getting much performance out of the receiver.

If you insist on using a random piece of wire, please get an "antenna tuner" which will match the impedance of the random wire (probably very high) to the radio (50 ohms, as stated)

Please clarify if that is how you are trying to operate the rig.

73, Jim AG3Y

Hi Allan,

In the case of strong received signals it's quite ok to "turn the s
meter down". Sometimes running a receiver wide open (maximum gain) is
not necessary. If I'm chatting with a local group on 80m and the QRN
is coming up I'll use the attenuator and RF gain to drop the
background noise enough so it doesn't annoy me. A much more pleasant
listening experience for sure. Alan says he is using his radio on
receive only so I think Bob's advice is good.

Some time ago there was one of those videos of "how to zero beat"
on you tube. It's been so long since I have been on that site since
moving to the rural area (stuck on dial up) I really cant say if it is
still there.

But if was very good at showing the "how to"

yioutta_99,

If you have replaced ALL the tubes...driver, both final amp tubes, you should: 1. do the "basic" alignment steps in the operators manual for the ANT, MIX, and DRIVE coils. Also, especially if you have changed the finals...neutralize them. Good luck.................

I did replace all tubes and they are neutralized. And will do the basics as you suggest

thanks

Don't adjust the small coils in the driver section unless you really have to. As old as the units are many of the slugs are stuck and you risk a chance of breaking one.

If you really do have to adjust these coils use a proper tuning tool. DO NOT USE A SCREWDRIVER!

Greetings group,

Problem: Rig will not "key-up" in CW with VOX "ON." Vox operates fine on sideband. The send/rcv switch has to be in SEND to use CW, but no side tone is heard..but there is full output. Voltage are on spec on the AF unit. Ideas??

Hi Joe,

It appears the CW side tone oscillator, Q12, on the FIX VOX Unit board is not working. A failure in the CW side tone oscillator will cause loss of CW Break-in. CW will still work, SEND switch OR PTT microphone button pressed in CW mode, and the 820 will still produce RF output as your 820 is doing but you will not have CW Break-in. Fix the side tone oscillator on the FIX VOX Unit board and CW Break-in will return.

I currently have a TS520, and would like to add the dg-5 for it. These units seem to be hard to come by. If one cannot be found or in my case a little out of my price range, what would be a good digital readout that could be substituted? All the ones that I have seen for sale were package deals included in the radio.

Thanks and 73,
Bryan-K8BEC

Mike,

Tnx fer the answer. I should have check the model # before sending. I was looking for the FIX-VOX unit...and could not find it..then found out that I had stated the wrong model #. The model is an 830S not 820S. So...possibly Q-1 on AF unit?

Morning Joe,

Yes, if Q1 fails then there will be no CW side tone which results in no CW Break-in even with VOX turned ON.

Q1 on the AF Unit board is a simple NPN transistor. I don't have a direct replacement, maybe someone else does, but a 2N3904 will work as a replacement. There is a difference in the pins between the 2SC945 and the 2N3904.

Looking at the bottom of the 2SC945 with the transistor's body flat spot up, leads towards you, the pins are labeled;

Emitter Collector Base

Look at the bottom of the 2N3904 with the transistor's body flat spot up, leads toward you, the pins are labeled;

Emitter Base Collector

Notice how the Base and Collector leads are reversed in the 2N3904 when compared to the 2SC945.

I have used 2N3904 NPN transistors to replace Japanese NPN transistors with very good result. I recently replaced a Japanese NPN transistor that had failed in a TS-120 CAR oscillator with a 2N3904 and the oscillator started working. If you go this route you have to arrange the 2N3904 Base, Emitter, and Collector leads so the correct leads are inserted into the correct holes in the PC board. But, if someone else has a direct replacement then I would go that route instead.

It's strange that you are having this problem. A ham on qrz.com is having a similar loss of CW side tone in his TS-130. I've been helping him with his loss of CW side tone which causes the TS-130, just like the TS-830 and other transceivers, loss of CW Break-in but does not result in loss of CW transmit in general.

30474. TS-520SE: 'Load' control always fully anti-clockwise. Problem?

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-03-28 17:41:51 UTC
From: andy_westcott2004
Topic: 30474 Message: 30474

Hi Guys.
Just a quick question for those more in the know than me:
I find that the load control always needs to be fully anti-clockwise for best output (on 80m and 40m, the only bands I use with it) - is this fairly mormal for these rigs or could it be indicative of a fixed parallel capacitor across the load control having failed open circuit?

It isn't a problem but it would be nice to see a peak before the control reaches the end of its travel, I'd be more confident the radio was operating at best efficiency.

Power output seems fine, by the way with no excessive plate current.

A DG-5 will plug into a TS-520S, if you have the 520 then you will need an adapter which is hard to find...

Will,

One other way to reduce the 830 to QRP levels is contained on page 20 of the TS-830 survival guide. In it, section 7.11 deals with one way to reduce power out to QRP levels. The text is, and I quote,"On SSB, turning down the mike gain is a poor way to reduce output power because doing so defeats the transmitter's ALC system. Thus, when you turn down the mic gain, you cannot assure any particular peak output level, and you're also turning down only the voice modulation content of your signal; the original carrier supression, unwanted sideband supression, misc transmitted noise, spurious and so forth are not adjusted "down" @ all, but remain as they were. As such, signal quality suffers. The best way to "turn down" the power of a TS830S.......is via the external ALC port onthe rig's rear panel. Providing an *djustable bias level to that port, ranging from 0 V DC to -10 V DC, will allow full-range power adjustment, down to zero output. This is accomplished with a 9 V transistor radio battery(POSATIVE terminal to chassis ground-ALC voltage supplies is negative) and a 1K ohm pot as wired as a voltage divider.

Tune up normally with poy adjusted for zero voltage @ ALC terminal, and should have about 100 watts out. With key down, adjust the pot until the power falls off to whatever power output you desire. Then, switch to SSB and your output will be that reduced level. DO NOT RETUNE anything on your rig, it's tuning will be just fine."

It closes by stating that the author(WB2WIK/6)had ran his rig that way for years and had no detrimental effects. It would provide all the audio punch and clarity, but @ reduced QRP levels. I have not tried it, but just thought I wouldf pass it along.

>

> Guys, pre suppose I wanted to do some QRP operating utilising my 830s;

> My questions would be: is it better to tune and load the rig, as normal, and then reduce the output power by screwing back the output power by use of the carrier control switch or, tune and load the rig to full output power and, using the ALC minus voltage feature (minus alc via the skt on the back of the rig) reduce power that way. I know the rig is not designed for this type of operating at large, but I am trying to understand if it will shorten bottle life or have any impact at all on the final output stage running QRP for a period of time. The ultimate answer is run an 817 or similar but you work with what you've got !!

The LOAD control setting at maximum RF output is at full CCW. Is this a bad thing?
Absolutely NOT. This simply means the load being presented to the transmitter's PI Network output is very close to 50 ohms.

However, having said that, I suspect the LOAD control is not exactly at full CCW but at some point CW from full CCW.

The "LOAD" control provides a means of providing as close of an impedance match, within the limited impedance range of the PI Network, to the load presented to the transmitter.

The adaptor may be difficult to find but one can build one. Simply duplicate the adaptor from the schematic and connect it accordingly.

Subject: [TS-520_820_530_830] Re: TS-520SE: 'Load' control always fully anti-clockwise. Problem?

The LOAD control setting at maximum RF output is at full CCW. Is this a bad thing? Absolutely NOT. This simply means the load being presented to the transmitter's PI Network output is very close to 50 ohms.

However, having said that, I suspect the LOAD control is not exactly at full CCW but at some point CW from full CCW.

The "LOAD" control provides a means of providing as close of an impedance match, within the limited impedance range of the PI Network, to the load presented to the transmitter.

Ok, thank you, that is what I was looking for.
Instead of "install instructions" it should be identified
as "how to build a DK-520 box"
thanks again
wd8aam

Hi Van,

The titles on the web page is "DK-520 Install and Service
Instructions" and just below that "Building the DK-520 for the TS520
instructions"

Lou

http://www.n6wk.com/kenwood/DK-520-Install-Instructions.pdf
The Above file tells how to wire it up.
This file tells how to build and install it.
I built the little power supply board on a small Perf board and mounted
it inside the metal box.
The Buffer board was also made from a small Perf Board and mounted as
shown in the below file
http://www.n6wk.com/kenwood/DK-520-Project.pdf
If there is enough interest, I might start making the boxes/Buffer
boards again and then it might make it easier for the 520 owners to
install the internal board and the Box

Gordon

30489. A MILESTONE FOR ME WITH TS-530S

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-03-28 22:01:28 UTC
From: Alan Nicholson (ADHB)
Topic: 30349 Message: 30489

Thanks Bob..and all the others who have provided guidance.

As I mentioned I am learning and the information provided has helped immensely. Rest assured I will be seeking some local one on one tuition and John Swarbrick in Hamilton has been a big help in clarifying some issues by email. Local club night is next Monday so hopefully I can take another step forward!

I am building a simple Dipole and hope to have it erected one night this week. Meanwhile last night, thanks to info provided here and from John I managed to pick up a few signals of varying strength and quality on 40 metres.

Terry K9TW- you do yourself a disservice. Without the advice you provided I would not be where I am now. It gave me the basics to start and the confidence that I would not blow up the rig in the process :-)

Thanks for your patience and willingness to suffer though my learning process- hopefully one day I will be able to give rather than take from the group.

73

Hi Van,

You sent me a PDF and at the top of the third page I can see the two documents. BTW, once you've downloaded the two articles check where the board is installed inside the radio. One 520 I worked on had a preamp board already installed. You never know, you might be lucky.

Date: 2011-03-28 21:43:28 UTC
From: scortesi1
Topic: 26914 Message: 30491

I would like to recognize the fine post by Mike (W5RKL) concerning adding the phone patch interface to the TS830 (message # 26923). I use the phone patch connections on my TS820 for a PSK 31 interface, it works very well.

I recently acquired a TS830 from a friend, and wanted to use a similar interface. Although I could build a cable to do this, I just don't like connecting to the front of the rig every time I want to do PSK31. Mike's very accurate instructions of where to connect on the IF board saved me hours of research had I done this on my own. I started on the TS830 Saturday morning and had it completed by early evening. My first contact was a station in Australia on 40M, said my signal was very clean.

A warning for anyone else who does this: Be sure you discharge all the HV caps before you remove the IF board. I remembered to do this for the final HV caps, but forgot about the plate voltage to the driver. The caps that supply this voltage have no bleeder resistors. I received a nice little reminder that I will not forget when I lifted the IF board out of the unit. Fortunatly I only received a small jolt, I then discharged the caps with a 10W 100 ohm resistor.

Thanks again Mike for all the contibutions you make to this group, they are very helpful.

Nope,j/k...:)..I wanted to throw that out there to see how many people would reply,unless the 3rd one is hiding from me somewhere.hihi. I must have a good set of tubes in mine. Into the dummy load on 40 and 80m it will load up to 150 watts. I usually will peak it out and then back it off a bit. No need to overdrive it.

30500. FS: TS511S, matching VFO/Speaker

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-03-29 00:43:46 UTC
From: john
Topic: 30500 Message: 30500

I hope this is appropriate for this forum... i

I have a nice condition TS11S with its matching VFO and speaker for sale. It has all interconnecting cables and while a brief test did not show any function with its internal VFO, I was copying stations switched to the external VFO (this may have been operator error, but no guarantees). I have copies of the manuals. All knobs are original and I see no modifications.

This is an unusual station and I'd keep it if I didn't have many lbs of "unusual stations" . I will have it available for pick up at the Raleigh NC Hamfest in April, if not sold before then. I'd like to get $395 plus actual shipping charges, and I will pack carefully to make sure it gets to you intact.

Pictures aren't ready yet, but will be shortly...write if you'd like them.

Thanks for the read!
John k5MO

Hi All,

I am planning to cut the output of my TS-830S by using the voltage divider at the rear ALC port as described today, so I can get 2-5 watts for my TenTec 6M transverter. I am worried about the 9 volt battery going bad, letting the power increase and burning up the transverter. I thought I might use a 9 volt wall wart instead as a power source, but even that could go bad, so what's the alternative? Use a line fuse going into the transverter? What value would I use, then?

Topic: 30474 Message: 30502

Dear amigo:
My advice... find yourself a Variac, that is a variable autotransformer, and connect your
transceiver to the Variac set to 10 volts... If possible for you, insert an AC ammeter
in series between the transceiver and the Variac...
Gradually increase the voltage to about 25 volts and watch the current reading.
Keep it at 25 volts for about 12 hours.
Next step: Move to 50 volts, and watch the current reading...
Calculate the power drawn from the Variac...
Then, disconnect the radio, open up the two covers and do a very careful visual
inspection around each and every electrolytic capacitors, especially the big high voltage ones...
Next step: Reset the Variac to 10 volts and gradually increase the voltage to
50 volts, leave it there for about 5 minutes and increase the voltage to 75 volts, carefull monitoring the current drawn that shows up on the AC ammeter.
Leave it there for about 12 more hours.
Next step: Do a second round of careful visual inspections , again especially around
electrolytics for any signs of leaks or of inflating capacitors.
Next step: Start slowly at 10 volts and climb up to 100 volts, and at this voltage
setting try the receive functions of the transceiver...
Almost the last step: IF the receive functions work OK, then give a short try to
the transmit function at a low power setting
Finally ... set the Variac to 115 volts , place the rig in receive mode, and monitor
the AC current shown on the ammeter.
Start to transmit , adjusting the rig for about 50 Watts output on 40 meters
and again measure the AC current shown on the ammeter.
If all goes well, your transceiver has REVIVED , because among other things the electrolytics were properly reformed...
This procedure is lengthy , tedious but it does avoid possible damages, especially
within the high voltage areas of any hybrid transceivers like our Kenwoods !!!

Hi Roy,

Most wallwarts have poor regulation and if you use one you might end up with unexpected power fluctuation perhaps even at 60Hz - not good. The current drain on a 9V battery is really low - so low that the battery will probably last it's shelf life. If you are really concerned about the battery going bad you could always go to the store and buy a new one every other month or so depending on how often you use it.

Lou
VK3ALB

P.S. Have you tested your TenTec transverter with the transverter output from the 830? It might just work OK for you then you can forget the whole 9V battery idea.

At 12:54 29/03/2011, you wrote:

Mike,

When I am around radios...I consider anything that goes wrong..normal...hihi. Another question: you stated that a 2N3904 to be a replacement..just the pins are different arrangement. I looked at the NTE cross ref. on the 2SC945 and came up with an NTE85, and also checked the cross on the 2N3904 and got an NTE123AP. the '85 is listed as audio amp, the 123AP listed as audio amp/switch. Would it make much of a difference between the two? I can not find the spare AF board I thought I had to swap.

It's strange that you are having this problem. A ham on qrz.com is having a similar loss of CW side tone in his TS-130. I've been helping him with his loss of CW side tone which causes the TS-130, just like the TS-830 and other transceivers, loss of CW Break-in but does not result in loss of CW transmit in general.

This was obviously Kenwood's Super TS-520, dubbed in closed manufacturing discussions as the STS-520, with push-pull 12BY7's driving the three 6146's in ultra-linear fashion with a specially designed hypersil power transformer to prevent RF output saturation and internal auroral radiation. Truly a marvelous piece of equipment to own if one can one to procure.

Hi Joe,

Yes I did say I used a 2N3904 as a replacement for a failed carrier oscillator in a TS-120. However, I also said if someone came up with a direct replacement to use the direct replacement. Therefore, if a direct cross reference replacement for a 2SC945 appears to be an NTE85 then I would use that. Pay close attention to the leads, Base, Emitter, and Collector to ensure they are the same as the 2SC945. It's easy to install the leads incorrectly.

All this and only 120 watt PEP "INPUT" on side band and 100 watts DC "INPUT" on CW.

As "Josephine" said in the movie Tombstone, as she gazed at Wyatt Earp in the distance on Allen Street, "I want one!".

[TS-520_820_530_830] A MILESTONE FOR ME WITH TS-530S

Cellphone and Shortwave (HF) reception are cojmpletely different phenomonons, apples and oarnges. You can live in a valley and have HF signals loud and clear from long distances away..
Hi Jim,

I'm glad I am not the only one confused:-)

Just to clarify - I am ONLY using the rig to receive as I am not yet licenced. I believe from information given here and elsewhere that a random length of wire is OK to receive(but not for tx) but I am in the process of making up my first Dipole. Poor weather put that on hold this weekend! Also we live in a dip and the reception for cellphones is marginal so I assume that the reception for a random wire antenna probably leaves a lot to be desired.

Precisely, which is why I was becoming slightly concerned that the best match I could achieve was with the LOAD control fully anti-clockwise. Not nearly so, but fully so.

I know the LOAD cap is padded out a bit and I was wondering if maybe one of the padding caps had failed, meaning I could not get enough 'C' to properly match the pi network. Essentially though, I was wondering if anyone else's 520 did the same thing - if not, this would point to a fault with mine.

I'll have a peep sometime and see if any of the caps are physically disconnected.

Topic: 30349 Message: 30513

Unless you have a serious problem due to some other condition, I would like to emphasize that your lack of sensitivity is very likely due to an impedance mismatch between your random length wire, and the input of your radio.

A dipole antenna is only going to give you the proper 50 ohm match on a single frequency or an odd multiple of that frequency. In the ham bands, a dipole cut for 40 meters (7 Mhz) will work quite well on 15 meters (21 Mhz) because 15 is an odd multiple frequency of the 40 meter band. That has been the traditional relationship of the old (pre WARC) amateur bands.

One way to get around this, is , as I believe I mentioned before, by using a antenna tuner, which is , in realilty, an impedance matching device, that will convert the highly reactive, high impedance source (the random wire) to a level that the radio can operate with satisfactorily.

The reason such an antenna is NOT a good idea for transmitting, is that RF will radiate from the wire, EVERYWHERE that the wire is exposed. This commonly results in a situation called "RF in the shack" which is exactly what it sounds like, and generally wreaks all kinds of havock on equpment. (computers resetting, lips and fingertips getting burned on metal objects such as microphones and knobs, etc.)

Hope this helps. 73, Jim AG3Y

[TS-520_820_530_830] A MILESTONE FOR ME WITH TS-530S

Cellphone and Shortwave (HF) reception are cojmpletely different phenomonons, apples and oarnges. You can live in a valley and have HF signals loud and clear from long distances away..
Hi Jim,

I'm glad I am not the only one confused:-)

Just to clarify - I am ONLY using the rig to receive as I am not yet licenced. I believe from information given here and elsewhere that a random length of wire is OK to receive(but not for tx) but I am in the process of making up my first Dipole. Poor weather put that on hold this weekend! Also we live in a dip and the reception for cellphones is marginal so I assume that the reception for a random wire antenna probably leaves a lot to be desired.

What is, as you said, is "best output"? In other words, what is the power output on 80 and 40 meters into a dummy load watt meter? "Best output" can be any level of power output from 5 watts to 100 watts, especially if there is a problem with your 520SE.

Do you achieve a good dip in IP current after peaking ALC with the DRIVE control in TUNE mode?

30518. Full ALC deflection when tuning

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-03-30 00:00:01 UTC
From: Chris Parnell
Topic: 30518 Message: 30518

Hi all,

I have my 830 working again after some time, but think I may have an issue with tubes... and would like guidance.
The issue is that when I flick to the send button (TX) I get full ALC deflection, regardless of mode, regardless of whether the heater is on or off on the front panel.

I can tune the rig to around 50W output on 20 meters, but the ALC full deflection is still there.

Is this an issue with the two 6146 tubes? any ideas?

Thanks
Chris Parnell, ZL1CDP

I had that fixed cap on the 80M bandswitch position blow out on me.
It caused me to have max setting on the load (CCW) and not get near the full 100 W on the lower part of the band (where the good stuff is).

In the useless part of the band (phone region) I could get full output with less then full CCW but nobody up there knows Morse !
It is not easy to get to on the TS520 but I managed to change it.

If one of the capacitors in the output of the Pi-Network opens you can add a capacitor by installing a "T" connector on the back of the rig and connect the replacement capacitor to one side of the "T".

That's a good diagnostic experiment, I'll have a mess about. I'll probably attatch a 100pF or so variable across the LOAD cap to see what happens, if anything - that'd be simpler for me to lash up as I have no T connector.

Thanks for the answers so far - I'll try to address some questions:
I get the same result whether using a dummy load or an antenna, but then my antennae exhibit a near unity match. (variable antenna base tuning)

The max power I get seems about 100 or possibly even higher using full carrier and peaked drive, (coarsly measured using an SWR meter - relative only of course) so if there is any matching error, it's small.

I only get the 'problem' on 80 and 40 (not tried 160), 20m peaks just prior to fully anti clock-wise.

I'll post any results of my messing once I've had the rig apart.

If you have the problem on both 40M and 80M that sounds like the 40M load capacitor since it is used on all lower bands.

>

That's a good diagnostic experiment, I'll have a mess about. I'll probably attatch a 100pF or so variable across the LOAD cap to see what happens, if anything - that'd be simpler for me to lash up as I have no T connector.

Thanks for the answers so far - I'll try to address some questions:
I get the same result whether using a dummy load or an antenna, but then my antennae exhibit a near unity match. (variable antenna base tuning)

The max power I get seems about 100 or possibly even higher using full carrier and peaked drive, (coarsly measured using an SWR meter - relative only of course) so if there is any matching error, it's small.

I only get the 'problem' on 80 and 40 (not tried 160), 20m peaks just prior to fully anti clock-wise.

I'll post any results of my messing once I've had the rig apart.

Selling the complete station as a whole or willing to part out.

TS-520
MC-50
AT-200
VFO-520
SP-520

All are in good physical and operational condition.

450.00 takes the whole setup plus shipping.

So now,

I replaced the 12BY7 driver tube with one from the stache and now I have stable output as well as usable output from the transverter connector! While I was in it I made a small, more fussy tweak to the neutralizing adjustment and the old tx is getting happy.

In the next couple of days I will go over the coil packs. When I installed the new finals last year I didn't do that and now I also have a new driver. The power out on the various bands is not even. I need a new set of screwdrivers so I'll break those in on the coil adjustments.

April Fool. No screwdrivers going near those coils!

As time permits I am going to build an outboard QRP final amp and use that instead of the ALC trick to reduce power. I expect to use a 5763 tube as the final. I will try to build that accessory so that it can be used with other low level "exciters".

Topic: 30531 Message: 30531

While perusing our local craigslist this week, I found an ad for some ham gear for sale. Seller listed a Kenwood TS-830S, a VFO-240 and an AT-230, along with some other goodies (and baddies).

Well, I contacted the seller, who had already fielded dozens of calls wanting to low-ball him an offer -- it was his late grandfather's station, and the grandfather had passed away while the man was in the Army. Now that he's out/retired, he's getting rid of all the stuff he inherited, including his Ham station.

So, we talked a bit, and he told me to come and take a look. So I did. I guess he liked me shooting straight with him, as I made him an offer on the gear and he sold it to me.

Turned out the 830S is a Gold Edition and looks to be in nice enough condition. Everything looks to be well-used, but not abused, and most of it should clean up nicely. Grandfather was a CW operator, so the only filter in the 830S was a CW filter, so I'll be adding filters, assuming the rig checks out okay. And I've already got a VFO-240 and AT-230, so these will be redundant.

If the rig checks out well and cleans up as nicely as I expect it to, I'll probably keep it and sell my 530SP, which is in very nice condx, along with the extra VFO and AT.

Grandfather also had a big amp and tuner, and I hope *those* check out as well. Not sure what I'll do with those, yet, as I don't really have the setup to run QRO here, but might hang on to them anyway if I ever do. Might happen in a few years, once the kids are out of school and if I get my druthers and move out into the country somewhat. (I'm not CCR restricted, but I *am* XYL restricted. And I have other hobbies that will do better out away from the city anyway.)

So, for those of you who resurrect these rigs on a regular basis -- any suggestions for what I should or should not do? My thoughts were to blow the majority of the dust and crud out of the rig with compressed air, and then power it up (soft start? I do have a variac) and see what happens. I can do output tests easily enough into a dummy load, check the VFO for operation, check the TX freq with a counter I have. Any other major points I should consider? The gear has been sitting since 2003, so I'm concerned about caps. Am certainly interested in hearing what else I should look for or be concerned about. I bought the lot primarily for this rig (and the big amp and tuner, assuming both work) and the rest is gravy that I think I can sell and make my investment back (without necessarily selling my 530SP). But we'll see.

Thanks for reading.

Tony,
Sounds lie you are off to a good start.
I do the same with the air and then I check all the connectors for a tight fit sometimes unmating them and remating them to ensure proper seating. Then I check all screws that fasten any circuit boards to the chassis to ensure good grounding. Check all the electrolytics to be sure there is no leakage. I do not recall any socketed IC's in the 830.

Check K4EAAs site: www.k4eaa.com for tons of information,
Ken is perhaps the most knowledgeable person on these rigs.

Hi Jeff,

The full, lean-on-it-hard ratings for a 5763 might give you ten watts. Other tubes can more easily do 10 watts (output). A 2E26 can pass 10 watts on SSB in class AB1 and in class C on CW can be pushed a hair past 25 watts. A 2E26 resembles a scaled down 6146. For a smaller form factor and good 'safety margin' a pair of 5763s or 6AQ5s seems about right. Have you built transmitters before? If you have any building or repair skills at all it should be easy enough. A solid state amp would work, too, but I haven't looked at suitable transistors AND I have a lot of usable tubes already. It should be easy enough to hang a full 1.5 KW off that transverter but... um... why would you bypass the 100 watt amp you already have to do that?

My T-599 will not go much below 10 Watts when I turn the drive all the way down - maybe 8.5 or 9 watts. I have been detuning the Load cap by increasing the capacitance a little to get down to 5 watts. Moving that control to the slightly higher capacitance side retains the low pass filtering while detuning to the higher side reduces the filtering according to the ancient ones. If you are using mostly SSB reducing the drive is apparently not recommended. I have done that with amtor and packet using audio tones without any problems at all.

What trouble are you having with the ALC trick? I haven't tried that on mine yet but I plan to give it a try while it's on the bench. I have a brand new pot just for that. I'll look to see if I am having the same kind of problems or if I can reproduce the problems you are having and maybe help sort it out. Somebody else on the list might have an answer for that, too. The pot and battery on the ALC lines seems to be the simplest method.

Mike ,
This is the circuit i have built , not very happy as the linier pot 250K Ohm
does not give a fine enough setting between 100 watts and 0 watts.

The range between the 2 is less that 1/8 of the pots sweep. I would like a
larger arc of effect , (less senisitivity in the pot could improve this).

Jeff

One could use two pots; one for a "coarse" adjustment (gets you in the area) and a second pot of a smaller resistance as a "fine" adjustment. Or you can just use a single 5-turn or 10-turn pot to improve the "fine" adjustment. If you plan to operate QRP all the time, theoretically, since the finals are in parallel, you should be able to pull one of the finals out, and drop to power out to about 40 or 50 watts. Of course, circuitry in the area should be reviewed beforehand.

I don't know if Ken wanted everyone to know it was his birthday? I caught him on 80 meters this morning at 40 over S 9. Man Gordon you have a great sounding station. Just could not resist posting it, And I want to sit down someday and learn everything you and Ken know about Kenwoods, amps, etc. How many life times would it take? So I am wishing you both many more life times of fun and success.

Hi Jeff,

I'm experimenting with another circuit that uses a couple of fixed resistors, a transistor, and a 20K linear pot. So far it works quite well, varies the voltage between -.16 to -5.5VDC. I want to do some more work.

It's a breadboard project at the moment, power is 9VDC from the board's built in power supply.

Hah Jeff,

It turns out my ALC circuit is inoperative. The 9 volt battery and pot trick has absolutely no effect. There is never any ALC deflection on any band during tuneup, either. I have just always tuned it up the way I have always tuned up other rigs with tube finals. I run it conservatively so I have not got myself in trouble overdriving it in SSB mode.

I'll dig into that later. I have the owner's manual AND the service manual so I'll get it. I suspect a fried transistor or a defective resistor. It is even possible the previous owner (long, long ago) disabled it so he could drive a CB amp harder (or some such foolishness).

With good tubes and fresh diddle of the coil pack she's running near 100 watts output at just over 200 mA so I am pleased. New problem, she won't go below about 30 watts with the carrier drive control all the way down now. I'm going to be after that transverter out put as soon as possible. I have an operating event coming up soon so it's about time to button up and get on the air.

Mike's idea with the transistor to control the ALC sounds like a good one.

So...

I just couldn't leave it alone. I found that I needed to clean the meter switch and now the ALC meter reading works as expected for tuneup. The 9 volt battery and pot still have no effect. Maybe the circuit in the T-599 is dramatically different or it's just plain broken. I'll look at that later. I put the covers back on for now.

I haven't thrown in the towel yet, but am still not done. All of the band switch seems ok, no broken couplers and it's properly aligned. I've replaced the caps that have been discussed on the antenna relay. I'd also noticed that someone had 6146A's in the rig, and found some good 6146B's. It's got all new cathode and screen resistors. I've neutralized the finals and found a dip, appears ok. However I'm still seeing less than 1w output. At least hasn't let the smoke out. LOL.

I wonder if I'm not getting drive through the final? I've removed and reseated all of the "board-to-board" coaxial connections I could find. Is this a common issue?

Thanks!

Bill,

take the ALC plug in out of the circuit when tunning up, , or the radio well not tune correctly.

only have this active after tunning .

Jeff

Hello Adam,

What position is the LOAD control when you start you tune up procedures?

Are you using a dummy load when tuning the transmitter?

What do you mean when you say you neutralized the finals and found a dip, appears ok?

If I remember correctly you said the band switch is aligned properly. How did you check the alignment of the band switch? When you adjust the PLATE control for a dip in IP current where is the PLATE control pointer pointing to? Is the IP dip a rather large dip (LOAD control set fully CCW) or only slightly noticeable?

Finding 6146As in the final will not cause the output to be only 1 watt, assuming the tubes are not bad.

Have you measured the voltages at the final tube socket screen and grid terminals in both receive and transmit with full output from the final amplifier?

What is the final tube HV when measured at the Rectifier Unit's "800" terminal? in receive and then in transmit with full output? Don't become confused at the low voltage measured at the Rectifier Unit's "HV" terminal as a problem. The Rectifier Unit's "HV" terminal is the voltage fed to the meter switch "HV" terminal and is not the HV voltage fed to the final tubes.

There should be more than enough drive to peg the ALC meter full scale to the right when adjusting the DRIVE control in TUNE mode with the CAR control set to 12 o'clock. Is this what happens when you key the transmitter (SEND switch UP) and adjust the DRIVE control in TUNE mode?

Are you using the 530 service manual schematic? If not then you should be using it when troubleshooting problems in your 530.

Hello Mike,

Sure, ceramic disc capacitors can fail...

About 40 years ago I built a Heathkit HW-101 kit. After testing and
alignment per the manual, it seemed the audio was quite bad. In fact, I
traced the fault to a 10 nF decoupling cap between the AGC line and ground.
I do not remember if this cap was a short or had some low resistance.
Heathkit was kind enough to send me another one (even if I had already
wired in a new one), but no reward for the time lost, hi !!

Just a side comment about the topic in progress.

30555. QRP control circuit

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-04-01 14:15:27 UTC

Topic: 30555 Message: 30555

I just uploaded a QRP control circuit "pdf" file to the files section. The file is named

"Kenwood Hybrid QRP control circuit.pdf"

The transistor is an NPN. I used an MPSW42 high voltage NPN transistor simply because I have quite a few of these on hand. A 2N2222A could also be used since the voltage and current demands are very low.

The adjustable "negative" ALC control voltage varies between approximately -.16VDVDC to approximately -5.5VDC depending on 9 volt battery voltage.

The parts are easily obtained from Mouser Electronics. A small Radio Shack experimental PC board can be used to mount the components. I built this circuit on my breadboard and measured the adjustable ALC output voltage with a DVM and an analog meter. I used the analog meter to visually see how linear the output voltage varies when adjusting the 20K pot.

The 20K pot can be a screw driver adjustable or a knob adjustable pot, it's entirely up to the builder. I used a screw driver adjustable pot and the ALC control voltage varies quite smooth.

Hi Jeff,

That's what I was doing. The add-on circuit with the pot and 9 volt battery has absolutely no effect at all. I am sure there is a problem with the ALC circuit in that regard. Because the transmitter works okay in all other respects I am going to put it back on the desk and work on some other gear - then come back to that pesky ALC circuit later. One of the "other" things is a small transmitter that I have used as "boots" for a QRP rig before but should itself reduce to QRP levels. Full power out was about 35 watts if I remember correctly. I intend to see what results I can get from the transverter output on my 599 using that. The other transmitter hasn't been turned on for quite a few years so I have all the questions about dried up electrolytics and etc. That particular TX runs in class C so it's only useful for CW. When I build a new one it will be switchable class AB1/class C.

Hi Mike,

I looked at the file for the QRP control circuit you posted. Looks like I could build that . . . . . what advantage does this circuit have over just using a 9v battery and a variable resistor to vary the voltage?

Also, what minimum and maximum output did you get? I'm guessing I would have to hook up a power meter in series with the output lead on 20M going to the antenna or dummy load to find a spot on the variable resistor dial where I would have the right output for my transverter.

I know this is real simple stuff to some of you, but I am still learning and want to make sure I have it right before something blows.

Although I can check my 9 v battery from time to time to make sure it doesn't go bad, what happens in this circuit if the voltage on the battery gets low?

Thanks for all your help.

73,
Roy

Hi Roy and Bill,

This circuit uses the "Grounded Collector" design, very similar to the hybrid's ALC amplifier and final amplifier bias control circuit.

The transistor in this circuit provide a more "linear" control over the negative DC output voltage applied to the remote ALC terminal. This circuit also control the "maximum output voltage" that can be applied to the remote ALC connection.

The original circuit can easily apply the full battery voltage, 9VDC, to the remote ALC connection. This is not possible with this circuit since the maximum output voltage is no higher than approximately -5.5VDC, even with the pot wide open, which is more in line with "TTL" (Transistor to Transistor Logic) voltage range. Normal TTL voltage range is from 0 to 5VDC. Yes, I am aware that there is an "invalid" voltage range from 0VDC to a point where actual low TTL voltage becomes "valid". The concept here is to keep the maximum output voltage much lower than the source voltage and the output voltage, when adjusted, to be more linear.

Most "typical" maximum peak ALC voltage levels fed to the external ALC connection is approximately -4VDC. This circuit fulfills those requirements nicely and again in a more linear fashion than the original circuit.

The output is taken from the transistor's 10K fixed Collector resistor/negative battery terminal junction and the transistor's 10K Emitter ALC output resistor.

I forgot to comment on what happens when the battery dies. Simple, the circuit stops working just as if the battery died in the original circuit. If there is no battery voltage then the transistor will no longer conduct and produce a negative voltage to the remote ALC connection again, just as if the battery died in the original circuit.

Please check out my now totally restored TS-530S in the photo album under my callsign. Many thanks to Gordon, N6WK for all his hard work on this radio. He did a first class restoration on a radio that was in very bad condition. You would never know it now! WOW!!

I'm sorry, I indicated the RED DC meter lead is connected to the 10K collector resistor and the "Negative" battery terminal. That's wrong. The RED meter lead is connected to the battery's "Positive" terminal and 20K pot junction. The rest is okay. Sorry for the wrong polarity and attachment point statement.

I purchased an audio comm boomset with dual earphones and boom mic a while ago to go with my ten tech omni 5. Being the mic has an electrec element it will not work with my kenwoods. Due to medical bills and disability I had to sell my ten tech. (I enjoyed my kenwood hybrids more anyhow) Is there a way to get power to the electret elementto make it work with my kenwoods? Or am I doomed to use the headset without the mic? I really like the receive audio on the headset and if the mic will work I would be very happy. I cannot afford a boomset to fit my kenwoods and I plan to keep them until I can no longer work ham radio. It's about the only enjoymant I still get to experience other than the company of my wife and children. Please give me an idea if you can. Thankyou KM5WX Richard

Hi Paul,

What transceiver will you be connecting a VFO-230 to? The VFO-230 will only plug into and work with a TS-530 or TS-830.

Hi Richard,

Unfortunately the 4 pin microphone socket is not designed to provide a DC voltage to power the microphone element in your headset.

The PTT voltage available on the 4 pin PTT microphone socket pin will not work either. When the PTT button is pressed, the PTT voltage is at "ground" potential leaving no voltage to power the microphone element in transmit.

You could change the microphone socket for a socket with more pins that matches the headset plug. After doing that you could tap the radio's 9VDC supply and apply that voltage to the new microphone socket's correct pins to power the headset microphone element. Mouser may have the socket you need.

Richard,

I know that there's a wiring diagram around here somewhere..I may have went to the great land fill...there's a guy...W2ENY I think, that makes mics with the electret element and powers it with an external 2 X AA battery. "GOOGLE" him and you can see what I'm talking about.....................also you make seen an example(s) on EBAY of his work.

Bill,

Where are you placing the + & - leads???

If you go by the circuit on the net the pins are shown in muirror image , Number 1 in actually lower right (just to the right of the notch in the plug) and you number from right to left anti clock wise, as you look at the socket.

this mucked me up as well when i originally fitted the circuit.

Jeff

Hi Jeff,

That's what I was doing. The add-on circuit with the pot and 9 volt battery has absolutely no effect at all. I am sure there is a problem with the ALC circuit in that regard. Because the transmitter works okay in all other respects I am going to put it back on the desk and work on some other gear - then come back to that pesky ALC circuit later. One of the "other" things is a small transmitter that I have used as "boots" for a QRP rig before but should itself reduce to QRP levels. Full power out was about 35 watts if I remember correctly. I intend to see what results I can get from the transverter output on my 599 using that. The other transmitter hasn't been turned on for quite a few years so I have all the questions about dried up electrolytics and etc. That particular TX runs in class C so it's only useful for CW. When I build a new one it will be switchable class AB1/class C.

Jeff,

Not getting full meter deflection may be caused by a couple of things: It's just is not putting out full output...check with wattmeter, or "RF VOLT" control pot on back of rig not adjusted...does not affect output...just the meter reading...Good luck

Jeff,

We need more information. You say you don't get full deflection, what
do you get? What is your meter switch and mode switch set to?

Your mode switch should be set to CW.

If it's set to IP them you should aim for around 220 to 225mA. Don't
go over 250mA as you'll decrease the life of your tubes.
If it's set to RF then you should look for a peak (not full) deflection.

30578. Fw: [TS-520_820_530_830] TS520S tunning issue

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-04-02 00:44:34 UTC
From: jeffrey lord
Topic: 30574 Message: 30578

Lou,

settings are correct when tunning , only getting 110-120 Ma , and dip on plate
tune is just visible.

Thanks,
Jeff

Jeff,

We need more information. You say you don't get full deflection, what
do you get? What is your meter switch and mode switch set to?

Your mode switch should be set to CW.

If it's set to IP them you should aim for around 220 to 225mA. Don't
go over 250mA as you'll decrease the life of your tubes.
If it's set to RF then you should look for a peak (not full) deflection.

Hi Jeff,

OK, so I assume you have run through the tune-up procedure correctly
and you are on CW with the meter set to IP and you're reading around
half the expected tube current.You said in your previous post that
you set the bias to 60mA. What was it before you adjusted it? Are
there two 6146 tubes in the radio and can you see the filament glow
in both? I wonder if you have a problem around the final tubes and
only one tube is drawing current or there is else something wrong
with the tube bias. Did the radio ever work, has something happened to it?

What could it be?

Only one tube in the set
Dead tube (maybe open filament)
Broken wire or bad socket on one tube
Some problem with the tube supply or bias.

I don't know your technical ability. Are you able to make
measurements around the tubes to check the voltages are correct or do
you have someone that can help you with these measurements? The
voltages around the tubes are deadly and if you're not confident of
your abilities I would really recommend to take it to a local amateur
that can help you.

30580. TV-506 cable into TV-502 cable

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-04-02 01:47:02 UTC
From: D
Topic: 30580 Message: 30580

So I've got 2 TV-506 cables when really I need 1 TV-506 cable and 1 TV-502 cable. Sounds like it's time to operate.
Looking @ page 4 of the TV-502 manual I can see the pin out list. Pin 6 states it goes to transverter in, so I suppose that goes to the center conductor of the RCA jumper, and make sure that pins 2 & 11 are clear.
The TV-506 manual does not include a pin out diagram. Can I assume that pin 1 goes to pin 1, pin 2 goes to pin 2, etc, and they don't jump over? I guess I'll see what it looks like in there when I open the plug.
Finally, WHY did Kenwood go to all that trouble to make a transverter cable that needed the extra RCA jumper to the xverter in jack, on the same chassis? Wouldn't it have been better to do that internally? It's not used for anything else but in this one instance...

From: n8ydadam
Topic: 30358 Message: 30581

I've kept a lower setting on the load control. Everything is done into a dummy.

I followed the neutralization instructions with tuning, turning SG off, and keying at 28.500. Then I adjusted the neutralization cap for minimal signal into my other reciever, as I don't have an RF voltmeter.

My ALC has been intermittent, but I've worked on cleaning RL-1, and it seems to be improving. The bandswitch seems to be aligned correctly, following your description. I'm getting a dip outside of the markings on the plate control. Attempting to dip on 20m, the plate control is pointing to 10MHz. I see a fairly deep dip. When I neutralized the tubes, the plate dipped in the proper (10m) section of the plate scale.

I checked the voltages on the 6146's a while ago, and came up with -103v (-55v on key down) at pin 3, and 262v (220v key down) at pin 5.

The voltage at AC800 on the Rectifier board is 476v (413v key down).

Sorry for my apparent ignorance on a lot of these things. Still learning! I appreciate all the help!

Adam, N8YD

I've replaced the caps that have been discussed on the antenna relay. I'd also noticed that someone had 6146A's in the rig, and found some good 6146B's. It's got all new cathode and screen resistors. I've neutralized the finals and found a dip, appears ok. However I'm still seeing less than 1w output. At least hasn't let the smoke out. LOL.

Richard,

I know that there's a wiring diagram around here somewhere..I may have went to the great land fill...there's a guy...W2ENY I think, that makes mics with the electret element and powers it with an external 2 X AA battery. "GOOGLE" him and you can see what I'm talking about.....also you make seen an example(s) on EBAY of his work.

Subject: [TS-520_820_530_830] Ts 530s/ ts 820s

I purchased an audio comm boomset with dual earphones and boom mic a while ago to go with my ten tech omni 5. Being the mic has an electrec element it will not work with my kenwoods. Due to medical bills and disability I had to sell my ten tech. (I enjoyed my kenwood hybrids more anyhow) Is there a way to get power to the electret elementto make it work with my kenwoods? Or am I doomed to use the headset without the mic? I really like the receive audio on the headset and if the mic will work I would be very happy. I cannot afford a boomset to fit my kenwoods and I plan to keep them until I can no longer work ham radio. It's about the only enjoymant I still get to experience other than the company of my wife and children. Please give me an idea if you can. Thankyou KM5WX Richard

hi Richard,

how about a small project box with the mic connector
on it and a pigtail with mic connector to the radio?

You can put the battery in the box and preserve the
original mic connector on the radio.

hi Dave,

I modified the interconnect tv-506 cable for my tv-502,
the cable is straight connection 1-1, etc.

I added the rca pigtail and it works great,
for the tv-506 just disconnect the rca pigtail.

Actually, I think that isn't correct. I believe that, like the DFC-230 and the VFO-240, the VFO-230 can also be used with the TS-130S. I will pull out mine later and double check, but I know I have used the first two with the 130S and am pretty sure that I have used the VFO-230 with it. The VFO-230 seems to be essentially the DFC-230 in a bigger suit.

I could, of course, be wrong.

Hi Paul,

What transceiver will you be connecting a VFO-230 to? The VFO-230 will only plug into and work with a TS-530 or TS-830.

Hi David,

That may be so but when considering the hybrids, the VFO-230 will only work with the 530 and 830. The 130 is not a hybrid, it's all solid state. That was the purpose of the question asking what transceiver Paul would be using the VFO-230 with.

30587. 520S voltage

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-04-02 04:15:42 UTC
From: Tom
Topic: 30587 Message: 30587

I was checking voltage on the transformer and found 350 Volts on the 800 Volt term. I checked AC input voltage and I have 118 Volts on one side of the power on switch with the switch in off and with the switch turned on I have 59 Volts on the switch output side. Maybe a bad transformer?

Thanks
Tom

Sorry about that. Having a 520S, 130S, 850S 130V, and 830S, I guess I tend to think of them collectively rather than as being only cousins. Hi!

Not that it matters, but I did double check my comment and can -- for whatever purpose -- confirm that the VFO-230 does work with the 130S. Oh, well . . . .

73,

Topic: 30587 Message: 30590

Hello Tom,
The characteristic signs of a "bad" transformer are:
(1) Shorted turn - transformer draws excess current and runs very hot, often blowing the protection device/fuse.
(2) Open primary or secondary - full voltage is applied to the primary winding, and no output on the secondary.

The symptoms you report suggest a high resistance in the switch (ie high voltage drop where there should be none.) I suggest you check the resistance of the switch, (power off and plug removed from wall socket), and inspect the switch, including the "sniff" test.

Hi Tom,

When you measure the high voltage are you measuring the voltage on the Rectifier Unit's "800" terminal or "AC800" terminal?

The power transformer has 2 primary windings. Each primary winding has 3 terminals, 120, 100, and 0. When measuring the "AC" voltage, the AC volt meter Black lead is connected to the "0" terminal and the Red lead is connected to the "120" terminal. With the main power switch turned ON, the voltage should be approximately 120VAC.

If the power plug has only "2" blades and both blades of the plug are the same size then it is easy to reverse the plug when inserting the plug into the wall outlet and end up with 120VAC on the transformer's primary 120 terminal and zero on the 0 terminal.

You can easily test the power switch. Unplug the 520 from the wall outlet. Ensure the main power switch is turned OFF. Connect an ohm meter across the power plug blades. If the switch is shorted in the "OFF" position you will see some resistance. If the switch is NOT shorted the ohm meter will show "infinity".

Leave the ohm meter connected to the power plug blades and turn the main power switch ON. The ohm meter should display approximately 8 to 10 ohms which is the resistance of the primary windings. Turning the main power switch OFF, the ohm meter should show "infinity". This is with the 120/240 rear panel switch set to "120". With the 120/240 switch set to 120, the transformer's primary windings are in "parallel". If you set the 120/240 switch to "240" the resistance will be higher because the transformer's primary windings are now in "series".

Lou, thanks for posting this information. I had never even heard of this freq. display unit prior to your posting. I, too, had been searching for a worthy DG-5 but had been coming up empty.
Anyway, I sent for the assembled unit and it arrived yesterday.It took me about 5 minutes to hook it up and I'm pleased to report that it works wonderfully, even on 10 meters with my TS-520SE.
I consider it money well spent and I'm looking forward to many years of service from this well constructed addition to my shack.
Thanks again.

Hi Tom,

350VAC X 1.4 X 2 = 980 VDC which is about right.

Remember this PS circuit is a voltage doubler.

What were the color codes and voltages on the secondary windings?

Phil

Sounds more like a switch problem if you are testing the line voltage
before and after the switch

LOU,

I do not have the expertise to check voltages in this area, only an f call at moment, .
All tubes show glow so are active ??,
Bias voltage was checked and has not changed was set several months ago and has not altered.

This issue started after trialing a circuit to reduce output to 10watts.

The set up was checked by another full ham, the radio was loading up correctly prior.

The circuit was checked and the fitting, by the full ham.

Jeff

Hi Jeff,

OK, so I assume you have run through the tune-up procedure correctly and you are on CW with the meter set to IP and you're reading around half the expected tube current.You said in your previous post that you set the bias to 60mA. What was it before you adjusted it? Are there two 6146 tubes in the radio and can you see the filament glow in both? I wonder if you have a problem around the final tubes and only one tube is drawing current or there is else something wrong with the tube bias. Did the radio ever work, has something happened to it?

What could it be?

Only one tube in the set
Dead tube (maybe open filament)
Broken wire or bad socket on one tube
Some problem with the tube supply or bias.

I don't know your technical ability. Are you able to make measurements around the tubes to check the voltages are correct or do you have someone that can help you with these measurements? The voltages around the tubes are deadly and if you're not confident of your abilities I would really recommend to take it to a local amateur that can help you.

I think that it is normal because HV winding on the transformer is prepared for doubling in the rectifier/doubler.
That was my concern also in my ts520. Marks on the transformer terminals are misleading (800V), in my Kenwood it was also about 400V AC on the transformer.
If you have problem with low HV DC, you should check diodes and electrolitic capacitors in rectifier/doubler.

Hi Mike,

Yeah, I should have mentioned earlier that my radio is the Trio TS830S.

Up untill a few years ago, I had the VFO-230 to compliment my setup, when I bought,it seemed like there were plenty to choose from and the avarage price seemed to be reasonable.

I went through a period of inactivity and decided that maybe I should sell up, had other interests going on and the radio wasn't being used,so the first item to go was the VFO. I regretted selling it when it had gone, so decided not to sell the other gear.

Anyhow, I'm back into the hobby, I'm located in the UK and having a hard time finding a VFO to replace the one I had.

I'v no idea of the price range per condition to expect.

Regards, Paul.

Hi Les,
Thank you for your help! The first thing i did was ohm out the power switch and it reads .2 Ohm then i read out the ac power cord (plug end) and it reads 2.1 Ohm. hooked up to the radio. Then I tore the AC power cable cinch plug apart and it was good. Then I replaced the power on switch with a toggle switch i had in my junk box and it reads the same. All of the voltages on the transformer read around 50 volts low except the 14 volt it reads 6 volts and the 800 volt reads 350 volts. I was thinking easy fix when i found out only half the line voltage is going to the transformer (bad ac line cord, switch or bad cinch plug) I checked the connections on the switch, the transformer and the cinch plug on the radio side. That is why I was thinking maybe the transformer was shorted? I double checked my readings from my VTVM with my Fluke meter.

Hello Tom,
The characteristic signs of a "bad" transformer are:
(1) Shorted turn - transformer draws excess current and runs very hot, often blowing the protection device/fuse.
(2) Open primary or secondary - full voltage is applied to the primary winding, and no output on the secondary.

The symptoms you report suggest a high resistance in the switch (ie high voltage drop where there should be none.) I suggest you check the resistance of the switch, (power off and plug removed from wall socket), and inspect the switch, including the "sniff" test.

That is why I was thinking maybe the transformer was shorted? I double checked my readings from my VTVM with my Fluke meter.

Topic: 30587 Message: 30601

Hi Mike,
Thanks for the reply! Sorry I had head up butt when reading the transformer voltages. I was reading voltages with the neg. lead still hooked up to the chassis ground lug. Here are the readings from the rectifier board.

800 14
reads 950Vdc reads 15Vdc

AC800 300 210 100 AC14
250Vac 250Vac 190Vac 90Vac 7.5Vac

To: TS-520_820_530_830@yahoogroups.com
Sent: Sat, April 2, 2011 6:42:12 AM
Subject: [TS-520_820_530_830] Re: 520S voltage

Hi Tom,

When you measure the high voltage are you measuring the voltage on the Rectifier Unit's "800" terminal or "AC800" terminal?

The power transformer has 2 primary windings. Each primary winding has 3 terminals, 120, 100, and 0. When measuring the "AC" voltage, the AC volt meter Black lead is connected to the "0" terminal and the Red lead is connected to the "120" terminal. With the main power switch turned ON, the voltage should be approximately 120VAC.

If the power plug has only "2" blades and both blades of the plug are the same size then it is easy to reverse the plug when inserting the plug into the wall outlet and end up with 120VAC on the transformer's primary 120 terminal and zero on the 0 terminal.

You can easily test the power switch. Unplug the 520 from the wall outlet. Ensure the main power switch is turned OFF. Connect an ohm meter across the power plug blades. If the switch is shorted in the "OFF" position you will see some resistance. If the switch is NOT shorted the ohm meter will show "infinity".

Leave the ohm meter connected to the power plug blades and turn the main power switch ON. The ohm meter should display approximately 8 to 10 ohms which is the resistance of the primary windings. Turning the main power switch OFF, the ohm meter should show "infinity". This is with the 120/240 rear panel switch set to "120". With the 120/240 switch set to 120, the transformer's primary windings are in "parallel". If you set the 120/240 switch to "240" the resistance will be higher because the transformer's primary windings are now in "series".

Date: 2011-04-02 12:27:32 UTC
From: Tom
Topic: 30602 Message: 30602

Mike & Les,
Well I tried to reply to both of you but I get Your form submission has expired so i will try it this way.

Hi Les,
Thank you for your help! The first thing i did was ohm out the power switch and it reads .2 Ohm then i read out the ac power cord (plug end) and it reads 2.1 Ohm. hooked up to the radio. Then I tore the AC power cable cinch plug apart and it was good. Then I replaced the power on switch with a toggle switch i had in my junk box and it reads the same. All of the voltages on the transformer read around 50 volts low except the 14 volt it reads 6 volts and the 800 volt reads 350 volts. I was thinking easy fix when i found out only half the line voltage is going to the transformer (bad ac line cord, switch or bad cinch plug) I checked the connections on the switch, the transformer and the cinch plug on the radio side. That is why I was thinking maybe the transformer was shorted? I double checked my readings from my VTVM with my Fluke meter.

Hi Mike,
Thanks for the reply! Sorry I had head up butt when reading the transformer voltages. I was reading voltages with the neg. lead still hooked up to the chassis ground lug. Here are the readings from the rectifier board.

Hi Jeff,

It's good that the tubes glow, at least the filaments are intact but there's still a problem. If the change in operation occurred after a modification then there's a good chance the mod caused the problem. Please confirm that the tube current you see isn't with the mod in place? Next, if you haven't already done so you should remove the mod and check the radio again. If after you've removed the mod and checked the radio you still have a problem you'll have to get someone familiar with valve radios to take a look at it. I doubt it's anything fatal but the next step is to make measurements and look for something wrong.

Hi Mike and All,

You all speak Radio real good, but my skills in that language are limited. I speak simple English a little better. I think I got the gist of what you were saying, but I want to make sure about one thing. If the 9 volt battery dies in this circuit, then the output goes to zero rather than to 80 to 100 watts, right?

Lou,

yes the circuit is plug-in and has been removed , the issue is still there,.
I have asked 1 of the full hams at the club to look at the set , but it may be a
couple of weeks before he can.

I will have to use my son's IC718 , in the mean time.

Many Thanks ,

Jeff

Hello Roy,

You said:

"If the 9 volt battery dies in this circuit, then the output goes to
zero rather than to 80 to 100 watts, right?"

No. If the battery dies in my circuit or the original circuit, the "negative" voltage applied to the remote socket "ALC" connection becomes "zero". This causes the transceiver's RF output to return to "normal" and NOT reducing to "zero".

Roy, if I may ask you a question. Have you been lead to believe that the higher the ALC meter indication the more power output the transmitter will produce? I ask this question because your question asks if the battery dies the transmitter's power output drops to zero. If you have been lead to believe the ALC meter indication MUST be at the top of the ALC scale during sideband transmissions then you have been mislead, given wrong information I'm sorry to say.

Righto Jeff,

I think it's significant that you're seeing about half of the
expected tube current. When you get to the bottom of it all please
post the resolution here. it might help someone in the future.

30609. Re: T-599 update

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)

From: Bill
Topic: 30529 Message: 30609

Hi Jeff,

T-599 is the transmitter for a set of twins. It has a separate transmitter and receiver that can be connected to operate as a transceiver. Each can be used independently or together. The connectors on the back are dramatically different from a monolithic transceiver like the 520. However, it has the same ALC circuit. There is an RCA type connector on the back that is in parallel with the ALC pins on the interconnect cable. I used the RCA connector with +9 to ground and the -ALC control voltage picked off the pot on the center terminal of that RCA connector. I may have something as "simple" as a broken wire inside from that RCA socket to the internal ALC terminal. I'll look some other time.

I have used the 520 and 820 and worked on a 520 a little bit for a friend. I used the 820 for an entire Field Day operation and I liked it. The twins have a lot in common with those. There are of course two VFOs and either can be used for transceive, or even swapped so that the receiver VFO controls the transmit frequency and the transmitter VFO controls the receive frequency. I would be too confused to try that! The DX hounds would use that feature to hopscotch up and own the band operating in split mode to catch that elusive DX. They can also be operated in transceive with the transmitter on a different band. Not a good idea on HF but maybe with converters on each unit for satellite work. I have an extra connector that I plan to use with the receiver and some other transmitting gear - the receiver controlling the operating frequency. There are quite a few hams who use the receiver alone and do not even have the T-599.

Thanks for your thoughtful comments.

73,

Bill KU8H

30610. TS-830S CW problem

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-04-03 01:37:44 UTC
From: Joseph Stiles
Topic: 30610 Message: 30610

Greeting group, & Happy B-day Gordon

This is a continuance of a prior thread...820S CW problem...that was a typo.

Problem: No keying of transmitter and no "sidetone" on CW with VOX "ON."
VOX works correctly when in SSB. When send/rcv switch is used, CW keying of transmitter works...but still no side tone. Q-1 on AF-AVR board was suspect and was replaced with an NTE85..still no joy. A known good AF-AVR unit was substituted and still same problem. I am currently out of ideas as my trouble shooting skills leave a bit to be desired. Any other suggestions?

30611. Update on my TS-830S find: Bandswitch

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-04-03 02:46:56 UTC
From: KA5TRO
Topic: 30611 Message: 30611

I have done an intial clean and check of the TS-830S Gold Edition that I found locally.

It was really fairly clean inside. A liberal application of compressed air helped a lot.

Opened up the HV section and did a visual inspection. Everything looked good. It looks like the gentleman took pretty good care not to overdrive the rig, and tuned it up well.

A quick load test showed full 100W output on 20M. I didn't test any other band, though, because I have a bandswitch problem -- it's *very* loose in the detents and if you don't have it *just so* the VFO won't be active. I did run it all the way around and while it does work on all bands it isn't as solid as my -530SP. So, I gather I'll either need a new bandswitch or to repair this one. Is there a way to do this? I haven't looked at it closely yet -- I just finished checking out the rig, and I've been working at stuff all day today and I don't want to go poking around in there just yet. If it's a replacement, I'm okay with that (I guess). If it's repairable, I'm not sure exactly how I should proceed. Suggestions?

Thanks,

Tony KA5TRO

Subject: [TS-520_820_530_830] Nice find!

While perusing our local craigslist this week, I found an ad for some ham gear for sale. Seller listed a Kenwood TS-830S, a VFO-240 and an AT-230, along with some other goodies (and baddies).

Well, I contacted the seller, who had already fielded dozens of calls wanting to low-ball him an offer -- it was his late grandfather's station, and the grandfather had passed away while the man was in the Army. Now that he's out/retired, he's getting rid of all the stuff he inherited, including his Ham station.

So, we talked a bit, and he told me to come and take a look. So I did. I guess he liked me shooting straight with him, as I made him an offer on the gear and he sold it to me.

Turned out the 830S is a Gold Edition and looks to be in nice enough condition. Everything looks to be well-used, but not abused, and most of it should clean up nicely. Grandfather was a CW operator, so the only filter in the 830S was a CW filter, so I'll be adding filters, assuming the rig checks out okay. And I've already got a VFO-240 and AT-230, so these will be redundant.

If the rig checks out well and cleans up as nicely as I expect it to, I'll probably keep it and sell my 530SP, which is in very nice condx, along with the extra VFO and AT.

Grandfather also had a big amp and tuner, and I hope *those* check out as well. Not sure what I'll do with those, yet, as I don't really have the setup to run QRO here, but might hang on to them anyway if I ever do. Might happen in a few years, once the kids are out of school and if I get my druthers and move out into the country somewhat. (I'm not CCR restricted, but I *am* XYL restricted. And I have other hobbies that will do better out away from the city anyway.)

So, for those of you who resurrect these rigs on a regular basis -- any suggestions for what I should or should not do? My thoughts were to blow the majority of the dust and crud out of the rig with compressed air, and then power it up (soft start? I do have a variac) and see what happens. I can do output tests easily enough into a dummy load, check the VFO for operation, check the TX freq with a counter I have. Any other major points I should consider? The gear has been sitting since 2003, so I'm concerned about caps. Am certainly interested in hearing what else I should look for or be concerned about. I bought the lot primarily for this rig (and the big amp and tuner, assuming both work) and the rest is gravy that I think I can sell and make my investment back (without necessarily selling my 530SP). But we'll see.

Thanks for reading.

Hello Tony,
I'd avoid using compressed air, or at least be very careful in using it.
In place of compressed air I'd use a clean dry paint-brush with moderately firm bristles.

In terms of "bringing up" your set, you have a variac, there are a good number of web-sites that describe the process, and how to re-form caps etc. Clearly you know about this process, and the knowledge that the process needs to be done is enough.

Les

Tony,

I should read my posting more carefully before pressing "send".

I should have added "and vacuum cleaner" in conjunction with the clean dry paintbrush.

I'm in the process of cleaning a very grotty BC-453, and it's amazing how much "crud" can be removed with patient vacuuming.

Hi Don,

Low RF output problems are not always caused by the weak/bad tubes.

Have you tried performing the COIL PACK adjustment, step 16 on page 36 and the GENERATOR DRIVE COIL ADJUSTMENT, step 18 on page 37 in the 830 service manual before replacing any of the tubes?

Do you have the 830 service manual? If not you can download it from Gordon's website, www.n6wk.com/kenwood/

Thank you for the reply
yes i saw that in the manual,but was not sure if i should do it
as you have confirmed it,i will give it a try
Not sure if someone fooled with it before as it is a Ebay special
The only reason i kept it,it has a dc transformer on it,very rare
as most are a/c only
thanks again

Topic: 30611 Message: 30618

Hello Tony,

The band switch "Detent" is on the final amplifier S22 band switch switch assembly. The other 6 band switch wafers on the RF Unit do not have any "Detents".

Again, the Detent consist of metal ball bearings on S22 in the final amplifier. The ball bearings are sandwiched between S22 metal frame and a flexible spring membrane. The switch assembly's metal frame has tabs around the frame's circumference. As the switch is rotated the balls roll over and fall between the tabs, hence the "Detent". If the flexible spring membrane is weak or one of the balls has fallen out then the band switch Detent will be affected.

Most switch detents have 2 balls 180 degrees opposite each other in the switch support frame. You can see the ball bearings on switch S22 in the final amplifier enclosure. Remove the final amplifier top cover then remove V1, front 6146, and look at switch S22 while rotating the band switch. You will see how the balls roll over the tabs on the metal frame of S22 as you rotate the band switch.

I recommend visually inspecting the coupler very closely while rotating the band switch. Cracks in the coupler may not be readily seen during an initial inspection. Cracks in the couplers typically are caused by over tightening the set screws, applying too much torgue to the set screws. A 1.5mm metric hex tool is required to loosen/tighten the set screws.

Remove the main power plug from the wall outlet and make sure the filter capacitors are discharged before attempting any work in the 830.

>
> A quick load test showed full 100W output on 20M. I didn't test any other band, though, because I have a bandswitch problem -- it's *very* loose in the detents and if you don't have it *just so* the VFO won't be active. I did run it all the way around and while it does work on all bands it isn't as solid as my -530SP. So, I gather I'll either need a new bandswitch or to repair this one. Is there a way to do this? I haven't looked at it closely yet -- I just finished checking out the rig, and I've been working at stuff all day today and I don't want to go poking around in there just yet. If it's a replacement, I'm okay with that (I guess). If it's repairable, I'm not sure exactly how I should proceed.

Suggestions?

>
>
>
> While perusing our local craigslist this week, I found an ad for some ham gear for sale. Seller listed a Kenwood TS-830S, a VFO-240 and an AT-230, along with some other goodies (and baddies).
>
> Well, I contacted the seller, who had already fielded dozens of calls wanting to low-ball him an offer -- it was his late grandfather's station, and the grandfather had passed away while the man was in the Army. Now that he's out/retired, he's getting rid of all the stuff he inherited, including his Ham station.
>
> So, we talked a bit, and he told me to come and take a look. So I did. I guess he liked me shooting straight with him, as I made him an offer on the gear and he sold it to me.
>
> Turned out the 830S is a Gold Edition and looks to be in nice enough condition. Everything looks to be well-used, but not abused, and most of it should clean up nicely. Grandfather was a CW operator, so the only filter in the 830S was a CW filter, so I'll be adding filters, assuming the rig checks out okay. And I've already got a VFO-240 and AT-230, so these will be redundant.
>
> If the rig checks out well and cleans up as nicely as I expect it to, I'll probably keep it and sell my 530SP, which is in very nice condx, along with the extra VFO and AT.
>
> Grandfather also had a big amp and tuner, and I hope *those* check out as well. Not sure what I'll do with those, yet, as I don't really have the setup to run QRO here, but might hang on to them anyway if I ever do. Might happen in a few years, once the kids are out of school and if I get my druthers and move out into the country somewhat. (I'm not CCR restricted, but I *am* XYL restricted. And I have other hobbies that will do better out away from the city anyway.)
>
> So, for those of you who resurrect these rigs on a regular basis -- any suggestions for what I should or should not do? My thoughts were to blow the majority of the dust and crud out of the rig with compressed air, and then power it up (soft start? I do have a variac) and see what happens. I can do output tests easily enough into a dummy load, check the VFO for operation, check the TX freq with a counter I have. Any other major points I should consider? The gear has been sitting since 2003, so I'm concerned about caps. Am certainly interested in hearing what else I should look for or be concerned about. I bought the lot primarily for this rig (and the big amp and tuner, assuming both work) and the rest is gravy that I think I can sell and make my investment back (without necessarily selling my

530SP). But we'll see.

Don,

Is your 830 an "S" or an "M" model? The TS-830M had an optional DS2 DC supply module that the "S" model did not have. If your 830 is an "S" model, more than likely a previous owner found and installed a DS2 DC supply module. You will need the TS-830M operator's manual to see how the DS2 DC supply module is connected.

If your 830 is an "S" model then the main power connection on the rear panel would also have to be changed.

If your 830 is in fact an "S" model, not an "M" model, then I recommend checking ALL of the DS2 connections and compare the connection to the TS-830M operator's manual, page 27. I also recommend checking the main power connector connection and compare them against the main schematic page 35, also in the 830M operator's manual, to ensure the connections are correct.

The DS2 DC supply module is not an optional accessory for the TS-830S.

yes it is a 830s with a ds2 which i found weird as i have not seen any like this
every thing looks the same except the power supply
now that you have told me it could have been modified i will check it as you say

thanks again for your time

Don,

I think you meant page "27". Page 28 is about wiring the TS-830S for 240VAC operation.

You are confusing the TS-830S service manual's receiver's COIL PACK adjustment step 16 on page 36 of the 830S service manual with the transmitter's driver coil adjustment, step 18 on page 37. A signal generator is not required to adjust the RF Unit transmitter's driver coil adjustment, step 18 page 37 in the service manual.

The receiver's coil pack adjustment, step 16 on page 36 should also be done when doing the transmitter driver coil adjustments, step 18 on page 37. This ensures both receiver and transmitter coil pack adjustments are correct.

You can use the 830's built-in Marker (calibrator) signal as a signal source if you do not have a signal generator when adjusting the "receiver coil pack" adjustment. Again, you do not need a signal generator or the 830's Marker signal when adjusting the Driver Coil pack adjustment.

Mike
i just checked the bottom of the transformer and it has been re soldered
i wonder if it was going to be used for the cb band?
my instruction manual gives the adjustments for sure on page 28 and next page 29 is analog dial and 220 operation on page 29??
This seems like it's going to be a bit of work
thanks Mike

30625. TS-520S voltage update

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-04-03 15:18:40 UTC
From: Tom
Topic: 30625 Message: 30625

I checked the Car. Board and the out term. reads 0 volts and T1 has no effect. This radio has no output on any band nor will it tune up and I can only get the bias down to 70 with the pot turned full counter clockwise. The SG switch has 260 volts on the top term. 260 volts on the middle term and -116 volts on the bottom term with the switch in the up position. With the SG switch in the down position it reads 260 volts top term. -116 volts on the middle and bottom terms.

Tom

Mike,

Thanks for your input.

Closer inspection does reveal that the coupler is, indeed, cracked, and has now failed completely.

I will go ahead and order a replacement. And I'll have to get a 1.5mm Allen wrench; the smallest I have is 2.0mm.

Pretty sure I understand how to discharge the filter caps, but to make sure I'm clear: I ground the line that goes to the final tube plate cap, correct?

Thanks.

Subject: [TS-520_820_530_830] Re: Update on my TS-830S find: Bandswitch

Hello Tony,

The band switch "Detent" is on the final amplifier S22 band switch switch assembly. The other 6 band switch wafers on the RF Unit do not have any "Detents".

Again, the Detent consist of metal ball bearings on S22 in the final amplifier. The ball bearings are sandwiched between S22 metal frame and a flexible spring membrane. The switch assembly's metal frame has tabs around the frame's circumference. As the switch is rotated the balls roll over and fall between the tabs, hence the "Detent". If the flexible spring membrane is weak or one of the balls has fallen out then the band switch Detent will be affected.

Most switch detents have 2 balls 180 degrees opposite each other in the switch support frame. You can see the ball bearings on switch S22 in the final amplifier enclosure. Remove the final amplifier top cover then remove V1, front 6146, and look at switch S22 while rotating the band switch. You will see how the balls roll over the tabs on the metal frame of S22 as you rotate the band switch.

I recommend visually inspecting the coupler very closely while rotating the band switch. Cracks in the coupler may not be readily seen during an initial inspection. Cracks in the couplers typically are caused by over tightening the set screws, applying too much torgue to the set screws. A 1.5mm metric hex tool is required to loosen/tighten the set screws.

Remove the main power plug from the wall outlet and make sure the filter capacitors are discharged before attempting any work in the 830.

>
> A quick load test showed full 100W output on 20M. I didn't test any other band, though, because I have a bandswitch problem -- it's *very* loose in the detents and if you don't have it *just so* the VFO won't be active. I did run it all the way around and while it does work on all bands it isn't as solid as my -530SP. So, I gather I'll either need a new bandswitch or to repair this one. Is there a way to do this? I haven't looked at it closely yet -- I just finished checking out the rig, and I've been working at stuff all day today and I don't want to go poking around in there just yet. If it's a replacement, I'm okay with that (I guess). If it's repairable, I'm not sure exactly how I should proceed. Suggestions?

> While perusing our local craigslist this week, I found an ad for some ham gear for sale. Seller listed a Kenwood TS-830S, a VFO-240 and an AT-230, along with some other goodies (and baddies).
>
> Well, I contacted the seller, who had already fielded dozens of calls wanting to low-ball him an offer -- it was his late grandfather's station, and the grandfather had passed away while the man was in the Army. Now that he's out/retired, he's getting rid of all the stuff he inherited, including his Ham station.
>
> So, we talked a bit, and he told me to come and take a look. So I did. I guess he liked me shooting straight with him, as I made him an offer on the gear and he sold it to me.
>
> Turned out the 830S is a Gold Edition and looks to be in nice enough condition. Everything looks to be well-used, but not abused, and most of it should clean up nicely. Grandfather was a CW operator, so the only filter in the 830S was a CW filter, so I'll be adding filters, assuming the rig checks out okay. And I've already got a VFO-240 and

AT-230, so these will be redundant.
>
> If the rig checks out well and cleans up as nicely as I expect it to, I'll probably keep it and sell my 530SP, which is in very nice condx, along with the extra VFO and AT.
>
> Grandfather also had a big amp and tuner, and I hope *those* check out as well. Not sure what I'll do with those, yet, as I don't really have the setup to run QRO here, but might hang on to them anyway if I ever do. Might happen in a few years, once the kids are out of school and if I get my druthers and move out into the country somewhat. (I'm not CCR restricted, but I *am* XYL restricted. And I have other hobbies that will do better out away from the city anyway.)
>
> So, for those of you who resurrect these rigs on a regular basis -- any suggestions for what I should or should not do? My thoughts were to blow the majority of the dust and crud out of the rig with compressed air, and then power it up (soft start? I do have a variac) and see what happens. I can do output tests easily enough into a dummy load, check the VFO for operation, check the TX freq with a counter I have. Any other major points I should consider? The gear has been sitting since 2003, so I'm concerned about caps. Am certainly interested in hearing what else I should look for or be concerned about. I bought the lot primarily for this rig (and the big amp and tuner, assuming both work) and the rest is gravy that I think I can sell and make my investment back (without necessarily selling my 530SP). But we'll see.

Well, Arnie, the first thing we need to find out is if the radio is working okay other than the digital display. Does it at least receive something? Does it transmit?

My first guess would be not a display module problem but a problem with the carrier module. Another possibility is the VCO/PD module. A loose connector on the VCO/PD unit will produce that kind of problem as well.
But in those cases the radio set will not do much of anything except possibly produce some static from the speaker.

Get back to us with more data and we will try and help you. This kind of problem with the TS-820S is not unusual and can be very easy to fix if you have some suitable test equipment.

Have you recently taken off the case? If so you may have put the longer screws in the bottom instead of the shorter ones and may have grounded a circuit trace. Does the "fixed" light come on as well?

Arnaldo;

1st try this link below to obtain data on cleaning the Display Unit (2 PC boards) in the TS-820

http://groups.yahoo.com/group/TS-520_820_530_830/message/28957

The DG-1, Display Unit is in a metal enclosure (2 PC boards inside) and provides the data to the digital display tube behind the front panel and above analog dial.

Very often, the internal connector pins inside the Display Unit are dirty. The 2 small PC board inside the Display Unit metal enclosure are separated by a metal enclosure wall in between the boards. The boards are connected through a set of "fixed" pins. Over time and environment, the pins and board connectors do get dirty and can cause problems such as you are experiencing.

You will need to remove the Display Unit, remove the outer covers, and remove each board, one at a time, cleaning the fixed pins and sockets on each board. Use care when removing the Display Unit as well as the boards. I recommend you use DEOXIT D5 Contact cleaner for the pins (a very small amount on each pin
with a Q-Tip) and then put the connector on/off a couple of times to help clean the pins/sockets in the
connectors. Also, on top of the Display Unit, you have a connector to the display tube that should be cleaned
with DeOxit, and on the bottom of the Display Unit. You have screws on the bottom of the Display Unit
that must be removed to take it out of the chassis.

Make sure you use canned (compressed) air and blow out any excess DeOxit D5 before applying any
power, it is very flammable. I normally let it set for several hours after using D5 so it can dry out
well.

Regards

Chuck, KJ4GU

Righto Jeff,

I think it's significant that you're seeing about half of the expected tube current. When you get to the bottom of it all please post the resolution here. it might help someone in the future.

I recently bought a set of Metric hex tools, 9 in all, sizes ranging from 1.5mm to 10mm at the local hardware store for $6. The hex tool set is made in the U.S. by BONDHUS GerillaProof Tools.

As strange as it may seem, American hardware stores and home supply houses do carry all types and sizes of Metric tools and at reasonable prices.

Greeting group, & Happy B-day Gordon

This is a continuance of a prior thread...820S CW problem...that was a typo.

Problem: No keying of transmitter and no "sidetone" on CW with VOX "ON."
VOX works correctly when in SSB. When send/rcv switch is used, CW keying of
transmitter works...but still no side tone. Q-1 on AF-AVR board was suspect and
was replaced with an NTE85..still no joy. A known good AF-AVR unit was
substituted and still same problem. I am currently out of ideas as my trouble
shooting skills leave a bit to be desired. Any other suggestions?

Joe,

With the 830 in CW, VOX turned OFF, volume control turned up a bit (hear hiss in speaker), short AF Unit plug 5 pin 2 to chassis ground. Do you hear the side tone? If you do then the "KEY" wire from AF Unit plug 5 pin 2 to the CW key socket is open, the CW key socket has a bad "KEY" terminal connection, or the CW key socket is very dirty.

I have experienced this problem before with my 820. I applied DeoXit D5 to the 1/4" plug shaft, inserted it into the CW socket then rotated the plug several times in both directions. I then tried keying the transceiver in CW mode and I could hear the side tone.

Hello... I'm new to this group and hope to learn more about my first Kenwood transceiver. I recently bought a very sharp looking TS-830S. It appears to have been well cared for and is operating quite well -- I'm super pleased with it.

I have noticed a slight problem in the transmit. Once in a while when I speak into the mike there's very little meter movement and the station on the other end says I've really dropped off. Cycling the speech processor on and off several times seems to cure it. Normally the transmit works great for a long period then all of a sudden the problem arises again and after cycling the processor switch several times the RF returns to normal.

I haven't used deOxit yet or done any cleaning inside of it. Does this sound like a dirty contact problem?

Thanks for any input,
WW8X Joe

I recently bought a set of Metric hex tools, 9 in all, sizes ranging from 1.5mm to 10mm at the local hardware store for $6. The hex tool set is made in the U.S. by BONDHUS GerillaProof Tools.

As strange as it may seem, American hardware stores and home supply houses do carry all types and sizes of Metric tools and at reasonable prices.

Yes but I would turn the 830 off and let it sit for 10 minutes. After 10 minutes, measure the voltage at the top of the final amplifier RF choke (round white cylinder with wire wrapped around it). The voltage should be very close to, if not, zero! If that's what you see then it's safe to work on the band switch coupler replacement and alignment.

Do you understand how to align the band switch assembly? If you have any questions, ask them before you start. You can easily end up with the entire band switch assembly being out of sync. I just went through this exact same problem with a local ham's 530 and he "thought" he knew how to do it but didn't. Again, ask if you have any questions.

> >
> > A quick load test showed full 100W output on 20M. I didn't test any other band, though, because I have a bandswitch problem -- it's *very* loose in the detents and if you don't have it *just so* the VFO won't be active. I did run it all the way around and while it does work on all bands it isn't as solid as my -530SP. So, I gather I'll either need a new bandswitch or to repair this one. Is there a way to do this? I haven't looked at it closely yet -- I just finished checking out the rig, and I've been working at stuff all day today and I don't want to go poking around in there just yet. If it's a replacement, I'm okay with that (I guess). If it's repairable, I'm not sure exactly how I should proceed. Suggestions?

> >
> > Turned out the 830S is a Gold Edition and looks to be in nice enough condition. Everything looks to be well-used, but not abused, and most of it should clean up nicely. Grandfather was a CW operator, so the only filter in the 830S was a CW filter, so I'll be adding filters, assuming the rig checks out okay. And I've already got a VFO-240 and AT-230, so these will be redundant.
> >
> > If the rig checks out well and cleans up as nicely as I expect it to, I'll probably keep it and sell my 530SP, which is in very nice condx, along with the extra VFO and AT.
> >
> > Grandfather also had a big amp and tuner, and I hope *those* check out as well. Not sure what I'll do with those, yet, as I don't really have the setup to run QRO here, but might hang on to them anyway if I ever do. Might happen in a few years, once the kids are out of school and if I get my druthers and move out into the country somewhat. (I'm not CCR restricted, but I *am* XYL restricted. And I have other hobbies that will do better out away from the city anyway.)
> >
> > So, for those of you who resurrect these rigs on a regular basis -- any suggestions for what I should or should not do? My thoughts were to blow the majority of the dust and crud out of the rig with compressed air, and then power it up (soft start? I do have a variac) and see what happens. I can do output tests easily enough into a dummy load, check the VFO for operation, check the TX freq with a counter I have. Any other major points I should consider? The gear has been sitting since 2003, so I'm concerned about caps. Am certainly interested in hearing what else I should look for or be concerned about. I bought the lot primarily for this rig (and the big amp and tuner, assuming both work) and the rest is gravy that I think I can sell and make my investment back (without necessarily selling my 530SP). But we'll see.

I have a couple of adjustable metric wrenches. One is a 30cm and another is a 25cm. Strangely, they look just like my English versions of the same design--12 inch and 10 inch Crescent wrenches to be exact. Yup, good old metric system coming to America!!

Hello Joe,

With the Processor knob turned OFF, the meter switch set to ALC, MIC gain set with you speaking in a normal voice about 1 to 2 inches from the MIC, the ALC meter should just start to flicker above zero. With that setting, do the distant stations hear you fine? This is assuming there is no local noise at the receiving stations. If so then the speech amplifier is working fine.

It is possible the Processor pot is dirty and needs cleaning. I would clean the Processor pot by applying a small amount of cleaner to the pot, rotating the pot both ways several times, then use canned air to remove any/all cleaner residue. Wait at least 3 to 5 minutes before applying power. Test the 830 with the processor turned ON to see if your problem goes away.

Remember it's not how LOUD you sound at the receiving end but how clean your transmit signal is. The MIC gain should be set so the ALC meter indication with you speaking at 1 to 2 inches from the microphone in a normal voice, should be just starting to flicker above zero. This is the point of maximum transmitter gain and maximum peak RF output. The higher the ALC meter indication the more reduction in RF output occurs.

>
> I have noticed a slight problem in the transmit. Once in a while when I speak into the mike there's very little meter movement and the station on the other end says I've really dropped off. Cycling the speech processor on and off several times seems to cure it. Normally the transmit works great for a long period then all of a sudden the problem arises again and after cycling the processor switch several times the RF returns to normal.

Yes but I would turn the 830 off and let it sit for 10 minutes. After 10 minutes, measure the voltage at the top of the final amplifier RF choke (round white cylinder with wire wrapped around it). The voltage should be very close to, if not, zero! If that's what you see then it's safe to work on the band switch coupler replacement and alignment.

Do you understand how to align the band switch assembly? If you have any questions, ask them before you start. You can easily end up with the entire band switch assembly being out of sync. I just went through this exact same problem with a local ham's 530 and he "thought" he knew how to do it but didn't. Again, ask if you have any questions.

Hi Joe,
Yes! Clean the Processor switch with some De-Oxit.
You'll find that is your problem. It is difficult to get some De-Oxit into some of those little switches, but it can be done through the little holes.
Be sure to exercise the switch after spraying some inside it .

Hi All,

I checked throygh the Manual, and found that somehow the Rf Voltage had been moved,
I folled the MAnual , and reset it for 2/3 meter reading .
The set now shows normal deflections on tune-up,
Previously I had less than 2mm deflection on the plate control , I now have a readable deflection , and full meter deflection is attainable when tuneing Plate & load controls in final tune step..

Cheers,
 Jeff

Hi mike
Don again
After adjusting all the coil pack this what i have come up with
1.8 full output 105 watts carrier in the center great
3.5,7.1 10.1,18,21,and 24 output is 90 watts with carrier fully
clockwise
If the carrier control is in the center i get half of that output 40 watts
Ten meters shows no drive at all ,but i can get 50 watts out
playing with the plate and load

30649. Full ALC deflection when tuning

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-04-03 23:36:17 UTC
From: Chris Parnell
Topic: 30518 Message: 30649

Hi everyone.... didn't get any responses to this question... just a quick update
The full ALC issue seems to be band dependent too... it completely pegs over on 20mts and on 15mts is a little on the high side but not pegged.

Any direction at all?

Cheers
Chris, ZL1CDP

30650. Receive alignment 520s

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-04-03 23:39:35 UTC
From: yioutta_99
Topic: 30650 Message: 30650

Hi all

After a successful tube change and neutralization, I decided to align the receive per the manual. I went through all the bands and tweeked the Antenna and mixer coils for max meter reading using the cal signal. I could not get the meter to move much if any except for the 20 meter band, that I could bring up a bit, the other bands didnt seem to respond. I did them in order, on the proper freq with the tuning tool. I hope i put the coilds back to where they should be. The cal signal was lowest on 28 mhz .

Also in the Hyterdyne, they give a band but not a freq to adjust the oscillator. when would I hear this oscillation? Are they talking about the Cal sig? They dont say to turn that on.

Thanks

Steve

any suggestions?

30651. Re: Update on my TS-830S find: Bandswitch

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)

There is a nice description of the bandswitch rebuild process along with pictures on Ken's site specifically at http://www.k4eaa.com/bandswitch.html (along with lots of other great service info on the site in general). If you're replacing the bandswitch rather than repairing it, the process should be even simpler.

well.
> > >
> > > A quick load test showed full 100W output on 20M. I didn't test any other band, though, because I have a bandswitch problem -- it's *very* loose in the detents and if you don't have it *just so* the VFO won't be active. I did run it all the way around and while it does work on all bands it isn't as solid as my -530SP. So, I gather I'll either need a new bandswitch or to repair this one. Is there a way to do this? I haven't looked at it closely yet -- I just finished checking out the rig, and I've been working at stuff all day today and I don't want to go poking around in there just yet. If it's a replacement, I'm okay with that (I guess). If it's repairable, I'm not sure exactly how I should proceed. Suggestions?

> > > Well, I contacted the seller, who had already fielded dozens of calls wanting to low-ball him an offer -- it was his late grandfather's station, and the grandfather had passed away while the man was in the Army. Now that he's out/retired, he's getting rid of all the stuff he inherited, including his Ham station.
> > >
> > > So, we talked a bit, and he told me to come and take a look. So I did. I guess he liked me shooting straight with him, as I made him an offer on the gear and he sold it to me.
> > >
> > > Turned out the 830S is a Gold Edition and looks to be in nice enough condition. Everything looks to be well-used, but not abused, and most of it should clean up nicely. Grandfather was a CW operator, so the only filter in the 830S was a CW filter, so I'll be adding filters, assuming the rig checks out okay. And I've already got a VFO-240 and AT-230, so these will be redundant.
> > >
> > > If the rig checks out well and cleans up as nicely as I expect it to, I'll probably keep it and sell my 530SP, which is in very nice condx, along with the extra VFO and AT.
> > >
> > > Grandfather also had a big amp and tuner, and I hope *those* check out as well. Not sure what I'll do with those, yet, as I don't really have the setup to run QRO here, but might hang on to them anyway if I ever do. Might happen in a few years, once the kids are out of school and if I get my druthers and move out into the country somewhat. (I'm not CCR restricted, but I *am* XYL restricted. And I have other hobbies that will do better out

away from the city anyway.)
> > >
> > > So, for those of you who resurrect these rigs on a regular basis -- any suggestions for what I should or should not do? My thoughts were to blow the majority of the dust and crud out of the rig with compressed air, and then power it up (soft start? I do have a variac) and see what happens. I can do output tests easily enough into a dummy load, check the VFO for operation, check the TX freq with a counter I have. Any other major points I should consider? The gear has been sitting since 2003, so I'm concerned about caps. Am certainly interested in hearing what else I should look for or be concerned about. I bought the lot primarily for this rig (and the big amp and tuner, assuming both work) and the rest is gravy that I think I can sell and make my investment back (without necessarily selling my 530SP). But we'll see.

30652. Re: Full ALC deflection when tuning

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-04-04 00:20:33 UTC
From: roberteleazer@rocketmail.com
Topic: 30518 Message: 30652

Not getting full ALC deflection on every band, especially the higher bands, is normal.

In fact for the TS-520, I believe that Kenwood has said that no ALC deflection is normal for 10M, although many people report getting substantial ALC transmit indications on that band.

Substantially less output on the higher bands is a common indicator of weak final tubes.

I assume the output you are measuring is CW. The only way to reliably measure SSB output is by feeding the mike input with middle, low and high frequency tones from an audio signal generator to explore the passband of the SSB filter. This is the procedure recommended by INRAD.

Is your ALC deflection steady or does it sag off after the first couple of seconds of transmit? If it does that is an indicator of a weak driver tube.

Finally, of course, you should consider aligning the driver coils.

Regards,

Robert

Topic: 30654 Message: 30654

I have a had a TS520SE for over a year now. It works well and puts out 100 watts across the board except 10 meters. nothing on 10. Last week it would not tune on 15. I could only get very low drive on 15. (tuning into a dummy load) I replaced the drive tube. seems much crisper on 40. On 15,I can tune about 100 watts into a dummy load even though the drive seems low.. Still nothing on 10.. I used Doxite on the band switch last night too. Rig looks brand new inside

Any Ideas?

k4YND

30655. Re: TS 520SE lack of drive in the tune position 10m and 15m

Yes but I would turn the 830 off and let it sit for 10 minutes. After 10 minutes, measure the voltage at the top of the final amplifier RF choke (round white cylinder with wire wrapped around it). The voltage should be very close to, if not, zero! If that's what you see then it's safe to work on the band switch coupler replacement and alignment.

Do you understand how to align the band switch assembly? If you have any questions, ask them before you start. You can easily end up with the entire band switch assembly being out of sync. I just went through this exact same problem with a local ham's 530 and he "thought" he knew how to do it but didn't. Again, ask if you have any questions.

I didn't test any other band, though, because I have a bandswitch problem -- it's *very* loose in the detents and if you don't have it *just so* the VFO won't be active. I did run it all the way around and while it does work on all bands it isn't as solid as my -530SP. So, I gather I'll either need a new bandswitch or to repair this one. Is there a way to do this? I haven't looked at it closely yet -- I just finished checking out the rig, and I've been working at stuff all day today and I don't want to go poking around in there just yet. If it's a replacement, I'm okay with that (I guess). If it's repairable, I'm not sure exactly how I should proceed. Suggestions?

> > Turned out the 830S is a Gold Edition and looks to be in nice enough condition. Everything looks to be well-used, but not abused, and most of it should clean up nicely. Grandfather was a CW operator, so the only filter in the 830S was a CW filter, so I'll be adding filters, assuming the rig checks out okay. And I've already got a VFO-240 and AT-230, so these will be redundant.
> >

> > If the rig checks out well and cleans up as nicely as I expect it to, I'll probably keep it and sell my 530SP, which is in very nice condx, along with the extra VFO and AT.
> >
> > Grandfather also had a big amp and tuner, and I hope *those* check out as well. Not sure what I'll do with those, yet, as I don't really have the setup to run QRO here, but might hang on to them anyway if I ever do. Might happen in a few years, once the kids are out of school and if I get my druthers and move out into the country somewhat. (I'm not CCR restricted, but I *am* XYL restricted. And I have other hobbies that will do better out away from the city anyway.)
> >
> > So, for those of you who resurrect these rigs on a regular basis -- any suggestions for what I should or should not do? My thoughts were to blow the majority of the dust and crud out of the rig with compressed air, and then power it up (soft start? I do have a variac) and see what happens. I can do output tests easily enough into a dummy load, check the VFO for operation, check the TX freq with a counter I have. Any other major points I should consider? The gear has been sitting since 2003, so I'm concerned about caps. Am certainly interested in hearing what else I should look for or be concerned about. I bought the lot primarily for this rig (and the big amp and tuner, assuming both work) and the rest is gravy that I think I can sell and make my investment back (without necessarily selling my 530SP). But we'll see.

Mike,

I'll be letting it sit for somewhat more than 10 minutes before I dive into that HV section. :-)

As far as alignment goes -- now that the coupler has failed completely, I'm going to assume that as long as I have the 'flat' parts in alignment, I'm good, right? :-)

I'll have to order the part anyway, so it will be a few days before I take a run at it anyway.

Thanks

Tony KA5TRO

Subject: [TS-520_820_530_830] Re: Update on my TS-830S find: Bandswitch

Yes but I would turn the 830 off and let it sit for 10 minutes. After 10 minutes, measure the voltage at the top of the final amplifier RF choke (round white cylinder with wire wrapped around it). The voltage should be very close to, if not, zero! If that's what you see then it's safe to work on the band switch coupler replacement and alignment.

Do you understand how to align the band switch assembly? If you have any questions, ask them before you start. You can easily end up with the entire band switch assembly being out of sync. I just went through this exact same problem with a local ham's 530 and he "thought" he knew how to do it but didn't. Again, ask if you have any questions.

Mark,

Yeah, I've seen that. I think that my entire problem is/was related to a cracked (now completely broken) shaft coupler. I'm not entirely sure I want to pull the whole thing apart, though it might not be a bad idea to do so while I'm in there anyway... it could probably stand a good cleaning and a touch of DeoXit.

I think I'll have a better idea after I get into it. I'll order the part from K4EAA and then wait until I receive it before diving into it. I've got another long week this week anyway...

Tony KA5TRO

There is a nice description of the bandswitch rebuild process along with pictures on Ken's site specifically at http://www.k4eaa.com/bandswitch.html (along with lots of other great service info on the site in general). If you're replacing the bandswitch rather than repairing it, the process should be even simpler.

Hi Robert,

The issue I am experiencing is that although I can tune for around 100W out, the ALC reading is pegged to the right on 20Mts... (regardless of whether I am in Tune, CW or SSB modes)... tuning for 100W out (more or less) has no effect on this ALC reading.

15 mts... as per above but less ALC reading (just less than fully pegged to right hand side).

Cheers
Chris, ZL1CDP

Mike,

Tnx fer the info...I'll get to it on Monday...this problem is driving me nuts. I do highly suspect the CW jack..as it seems to be a rather simple circuit.(one I can understand..at least partially) and appears not much can go wrong... AGN TNX!

Subject: [TS-520_820_530_830] Re: TS-830S CW problem

Joe,

With the 830 in CW, VOX turned OFF, volume control turned up a bit (hear hiss in speaker), short AF Unit plug 5 pin 2 to chassis ground. Do you hear the side tone? If you do then the "KEY" wire from AF Unit plug 5 pin 2 to the CW key socket is open, the CW key socket has a bad "KEY" terminal connection, or the CW key socket is very dirty.

I have experienced this problem before with my 820. I applied DeoXit D5 to the 1/4" plug shaft, inserted it into the CW socket then rotated the plug several times in both directions. I then tried keying the transceiver in CW mode and I could hear the side tone.

Topic: 30611 Message: 30661

Looking at the 830 with the final amplifier top removed and the 830's front panel facing you, the "flats" on the shaft of the final amplifier switch assembly, S22, must be exactly vertical on the right and exactly horizontal on the bottom of the shaft. I am NOT talking about the "long band switch shaft"! Some folks get confused when talking about "flats" since the long band switch shaft has a flat side. I'm talk ONLY about the shaft of switch S22 inside the final amplifier enclosure. Switch assembly S22 is the ONLY switch assembly inside the final amplifier.

The front panel band switch knob pointer must be pointing exactly at 10. Again, I'm NOT talking about 10 meters, which some folks tend to get confused about, when I say set the band switch knob to "10". There is only "1" band switch position labeled "10" on the front panel and that position is NOT 10 meters!

With these 2 things done exactly as I described and all 4 of the coupler set screws are tightened, the band switch is aligned properly. Any deviation from this will be wrong!

Symptoms you may/can experience if the complete band switch assembly which includes the 6 individual band switch wafers and S22 inside the final amplifier, are

1. Very weak to no IP dip when adjusting the PLATE control during tune up
2. Plate control, at dip, will NOT be pointing at the correct frequency label on the front panel you are attempting to tune the transmitter up on.
3. Plates of both final amplifier tubes can and most likely will, turn RED (a BIG NO-NO!!) when RF is applied to the final tubes.
4. Very little, if any, RF output to a watt meter and/or the RF meter switch setting.
5. High IP current even with very little RF output and very little, if any IP dip.
6. If transmitter is kept keyed and the final tube plates turn RED, the cathode resistors can overheat and be damaged plus the fuse could easily blow.
7. Excessive constant IP current can lead to overheating the RF choke in the final amplifier
8. Undue stress will be placed on the power supplies.

Some or all of the above may/can happen if the band switch assembly is out of alignment. I know from experience, items 1, 2, 3, 4 and 6 can easily happen when RF is applied (CAR control adjusted clockwise) during tune up, especially in CW mode.

Therefore, make sure you fully understand how the flats on the shaft of switch assembly S22 inside the final amplifier enclosure are to be and the band switch knob must point exactly at 10.

> Yes but I would turn the 830 off and let it sit for 10 minutes. After 10 minutes, measure the voltage at the top of the final amplifier RF choke (round white cylinder with wire wrapped around it). The voltage should be very close to, if not, zero! If that's what you see then it's safe to work on the band switch coupler replacement and alignment.
>
> Do you understand how to align the band switch assembly? If you have any questions, ask them before you start. You can easily end up with the entire band switch assembly being out of sync. I just went through this exact same problem with a local ham's 530 and he "thought" he knew how to do it but didn't. Again, ask if you have any questions.

> > >
> > > A quick load test showed full 100W output on 20M. I didn't test any other band, though, because I have a bandswitch problem -- it's *very* loose in the detents and if you don't have it *just so* the VFO won't be active. I did run it all the way around and while it does work on all bands it isn't as solid as my -530SP. So, I gather I'll either need a new bandswitch or to repair this one. Is there a way to do this? I haven't looked at it closely yet -- I just finished checking out the rig, and I've been working at stuff all day today and I don't want to go poking around in there just yet. If it's a replacement, I'm okay with that (I guess). If it's repairable, I'm not sure exactly how I should proceed. Suggestions?

Not sure what I'll do with those, yet, as I don't really have the setup to run QRO here, but might hang on to them anyway if I ever do. Might happen in a few years, once the kids are out of school and if I get my druthers and move out into the country somewhat. (I'm not CCR restricted, but I *am* XYL restricted. And I have other hobbies that will do better out away from the city anyway.)
> > >
> > > So, for those of you who resurrect these rigs on a regular basis -- any suggestions for what I should or should not do? My thoughts were to blow the majority of the dust and crud out of the rig with compressed air, and then power it up (soft start? I do have a variac) and see what happens. I can do output tests easily enough into a dummy load, check the VFO for operation, check the TX freq with a counter I have. Any other major points I should consider? The gear has been sitting since 2003, so I'm concerned about caps. Am certainly interested in hearing what else I should look for or be concerned about. I bought the lot primarily for this rig (and the big amp and tuner, assuming both work) and the rest is gravy that I think I can sell and make my investment back (without necessarily selling my 530SP). But we'll see.

The information shown on Ken's website is for removing the RF Unit. You do NOT have to pull the band switch shaft completely out as shown on Ken's website.

30663. Fixed channel operation

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-04-04 03:17:27 UTC
From: Bryan
Topic: 30663 Message: 30663

I am planning on using the fixed channel operation for my TS 520. I have the formula to figure the frequency for the crystal needed. Reading in the manual I also see that it just plugs in to the fixed board. After it is plugged in you just net the frequency to get it spot on. Is there a specific brand of crystal needed for this. Also where would one get the specific crystal needed. I have never done this before with any other Kenwood Hybrid, so just needing a little bump in the right direction and if there are any specific little tricks that makes it a little bit easier.

Thanks,
Bryan

30664. Finals on the way out TS 520S

Topic: 30664 Message: 30664

Hi,

I have a TS 520s. I've been having a lot of fun and working some good DX as 20m seems to be open currently.

Anyhow I've noticed that on 20m I seem to be able to get a max of 75w out. I'm measuring this with the power meter built into my antenna tuner.

I tune into a dummy load (I built a version of the Dummy load on K4EAA's website and I follow the tune up procedure on Ken's Site also).

What I notice on switching from the dummy load to the antenna tuner / antenna is that I get a peak of approx 100w which drops pretty quickly (3/4 Seconds) to 75w.. I suspect what I'm seeing is a tired Driver tube.

Does that sound likely...????

If so yep I can source replacement Tubes (Ebay etc) but I have no equipment assist in the process to neutralize them. Any thoughts on that would be greatful.

Thanks in advance

John

Roger that. I didn't think so. I know I'll have to pull the forward-most 6146B to access the coupler.

10MHz, not 10M. Right. :-)

Will check back in after I give this a run. Thanks again, all.

Ken's site specifically at http://www.k4eaa.com/bandswitch.html (along with lots of other great service info on the site in general). If you're replacing the bandswitch rather than repairing it, the process should be even simpler.

After 10 minutes, measure the voltage at the top of the final amplifier RF choke (round white cylinder with wire wrapped around it). The voltage should be very close to, if not, zero! If that's what you see then it's safe to work on the band switch coupler replacement and alignment.
> >
> > Do you understand how to align the band switch assembly? If you have any questions, ask them before you start. You can easily end up with the entire band switch assembly being out of sync. I just went through this exact same problem with a local ham's 530 and he "thought" he knew how to do it but didn't. Again, ask if you have any questions.

> > >
> > > Again, the Detent consist of metal ball bearings on S22 in the final amplifier. The ball bearings are sandwiched between S22 metal frame and a flexible spring membrane. The switch assembly's metal frame has tabs around the frame's circumference. As the switch is rotated the balls roll over and fall between the tabs, hence the "Detent". If the flexible spring membrane is weak or one of the balls has fallen out then the band switch Detent will be affected.
> > >
> > > Most switch detents have 2 balls 180 degrees opposite each other in the switch support frame. You can see the ball bearings on switch S22 in the final amplifier enclosure. Remove the final amplifier top cover then remove V1, front 6146, and look at switch S22 while rotating the band switch. You will see how the balls roll over the tabs on the metal frame of S22 as you rotate the band switch.
> > >
> > > I recommend visually inspecting the coupler very closely while rotating the band switch. Cracks in the coupler may not be readily seen during an initial inspection. Cracks in the couplers typically are caused by over tightening the set screws, applying too much torgue to the set screws. A 1.5mm metric hex tool is required to loosen/tighten the set screws.

I didn't test any other band, though, because I have a bandswitch problem -- it's *very* loose in the detents and if you don't have it *just so* the VFO won't be active. I did run it all the way around and while it does work on all bands it isn't as solid as my -530SP. So, I gather I'll either need a new bandswitch or to repair this one. Is there a way to do this? I haven't looked at it

closely yet -- I just finished checking out the rig, and I've been working at stuff all day today and I don't want to go poking around in there just yet. If it's a replacement, I'm okay with that (I guess). If it's repairable, I'm not sure exactly how I should proceed. Suggestions?

Now that he's out/retired, he's getting rid of all the stuff he inherited, including his Ham station.
> > > >
> > > > So, we talked a bit, and he told me to come and take a look. So I did. I guess he liked me shooting straight with him, as I made him an offer on the gear and he sold it to me.
> > > >
> > > > Turned out the 830S is a Gold Edition and looks to be in nice enough condition. Everything looks to be well-used, but not abused, and most of it should clean up nicely. Grandfather was a CW operator, so the only filter in the 830S was a CW filter, so I'll be adding filters, assuming the rig checks out okay. And I've already got a VFO-240 and AT-230, so these will be redundant.
> > > >
> > > > If the rig checks out well and cleans up as nicely as I expect it to, I'll probably keep it and sell my 530SP, which is in very nice condx, along with the extra VFO and AT.
> > > >
> > > > Grandfather also had a big amp and tuner, and I hope *those* check out as well. Not sure what I'll do with those, yet, as I don't really have the setup to run QRO here, but might hang on to them anyway if I ever do. Might happen in a few years, once the kids are out of school and if I get my druthers and move out into the country somewhat. (I'm not CCR restricted, but I *am* XYL restricted. And I have other hobbies that will do better out away from the city anyway.)
> > > >
> > > > So, for those of you who resurrect these rigs on a regular basis -- any suggestions for what I should or should not do? My thoughts were to blow the majority of the dust and crud out of the rig with compressed air, and then power it up (soft start? I do have a variac) and see what happens. I can do output tests easily enough into a dummy load, check the VFO for operation, check the TX freq with a counter I have. Any other major points I

should consider? The gear has been sitting since 2003, so I'm concerned about caps. Am certainly interested in hearing what else I should look for or be concerned about. I bought the lot primarily for this rig (and the big amp and tuner, assuming both work) and the rest is gravy that I think I can sell and make my investment back (without necessarily selling my 530SP). But we'll see.

If the power changes when connected to the antenna you probably have something in the antenna system heating up. The SWR will be changing.

Subject: [TS-520_820_530_830] Finals on the way out TS 520S

Hi,

I have a TS 520s. I've been having a lot of fun and working some good DX as 20m seems to be open currently.

Anyhow I've noticed that on 20m I seem to be able to get a max of 75w out. I'm measuring this with the power meter built into my antenna tuner.

I tune into a dummy load (I built a version of the Dummy load on K4EAA's website and I follow the tune up procedure on Ken's Site also).

What I notice on switching from the dummy load to the antenna tuner / antenna is that I get a peak of approx 100w which drops pretty quickly (3/4 Seconds) to 75w.. I suspect what I'm seeing is a tired Driver tube.

Does that sound likely...????

If so yep I can source replacement Tubes (Ebay etc) but I have no equipment assist in the process to neutralize them. Any thoughts on that would be greatful.

Thanks in advance

John

Hello John,

You said you think your RF output problem is a "tired driver tube". This is a typical quick fix to a problem that could easily not be caused by a tube. Unless troubleshooting results clearly point to a tube as the source of a problem, don't automatically waste time and money replacing tubes. More often then not, RF output problems are not caused by weak tubes. This is not to say RF output problems are never caused by weak or bad tubes. It simple means most RF output problem are not caused by weak/bad tubes, nothing more.

Try this simple and easy test.

1. Connect the 520 to a 50 ohm dummy load that can safely handle 100 watts for at least 30 second to a minute without overheating.

2. Set Mode switch to TUNE

3. Set the CAR control to 11 o'clock

4. Set meter switch to ALC

5. Flip the SEND switch UP (520 in transmit)

6. Adjust the DRIVE control for a peak ALC meter indication. If the meter pegs full scale to the right, rotate the CAR control CCW so the meter pointer points at 12 o'clock and continue adjusting the DRIVE control for a peak meter indicaiton.

7. Leave the 520 keyed and watch the ALC meter for a few seconds.

8. Flip the SEND switch DOWN, places 520 in receive

When performing item 7 above, does the meter start to drop back towards zero? If it does, regardless how slow or fast the meter moves, the driver tube is weak and should be replaced.

Perform the above simple test after the 520 has been warmed up for at least 30 minutes.

Bryan,

No particular "brand." just has to be the right "CASE." Go to "International Crystal Manufacturing Co.'s " web site, or call them at 800-725-1426. They are very helpful. You should be able to just tell them what kind of rig...Kenwood...TS520..etc... and for what you are using the crystal for. Be prepared to pay about $22.00.

Subject: [TS-520_820_530_830] Fixed channel operation

I am planning on using the fixed channel operation for my TS 520. I have the formula to figure the frequency for the crystal needed. Reading in the manual I also see that it just plugs in to the fixed board. After it is plugged in you just net the frequency to get it spot on. Is there a specific brand of crystal needed for this. Also where would one get the specific crystal needed. I have never done this before with any other Kenwood Hybrid, so just needing a little bump in the right direction and if there are any specific little tricks that makes it a little bit easier.

Thanks,
Bryan

After adjusting all the coil pack this what i have come up with
1.8 full output 105 watts carrier in the center great
3.5,7.1 10.1,18,21,and 24 output is 90 watts with carrier fully
clockwise
If the carrier control is in the center i get half of that output 40 watts
Ten meters shows no drive at all ,but i can get 50 watts out
playing with the plate and load

Should i try to adjust the carrier?

thank you

Mike,

Cleaned CW key jack with DEOXIT and blew out with "canned air." No change. Tested as instructed below, no change. I checked the voltage on pin 2-plug 5 with key plug out..."ZERO", with key plug in: -70v. With CW key plug in and pin 2 is shorted to ground, I can hear a "crackle" in the speaker...but no side tone or keying(QSK) The wire on plug 3 is OK.

Subject: [TS-520_820_530_830] Re: TS-830S CW problem

Joe,

With the 830 in CW, VOX turned OFF, volume control turned up a bit (hear hiss in

speaker), short AF Unit plug 5 pin 2 to chassis ground. Do you hear the side tone? If you do then the "KEY" wire from AF Unit plug 5 pin 2 to the CW key socket is open, the CW key socket has a bad "KEY" terminal connection, or the CW

key socket is very dirty.

I have experienced this problem before with my 820. I applied DeoXit D5 to the 1/4" plug shaft, inserted it into the CW socket then rotated the plug several times in both directions. I then tried keying the transceiver in CW mode and I could hear the side tone.

If you turn VOX OFF, plug in a CW key, set the MODE switch to CW, flip the SEND switch UP then press the CW key, do you see RF output? If so then the normal CW keying circuit is working properly. Now you need to track down why the CW side tone oscillator is not working. Since VOX appears to be working in sideband, it's not the VOX circuit that's causing the problem.

If you watch yourself in a mirror while using the "left handed" wrenches, the wrenches now become "right handed" wrenches!! No need to buy more expensive "right handed" wrenches, simply use a mirror. You have a mirror don't you??? Talk about a "quick fix", that's one you may not have thought of!!!

Mike,

The answer is: When mode switch to CW...send/rcv...to SEND...and key is depressed..transmitter is keyed with adequate (98W/20M)... output. Just no side tone. Is Q1 on the AF-AVR board the "SIDE TONE OSCILLATOR?" or just a "switch" for the VOX circuit? Do I need to look elsewhere. I am not the best at diagnostics...but I am getting better..thanks to you and the group.

They may seem left-handed, but I think you'll find that those wrenches were actually designed for use on the back of the radio.

Joe,

Q1 is on the AF board and Q1 is the side tone oscillator. If the side tone oscillator fails for what ever reason, there will be CW side tone resulting in no CW break-in.

Mike,

I think I should check the voltage levels as listed for the Q1. Maybe...the "known good" AF-AVR board Q1 was/is bad also....just my luck...Oh well..........gives good experience....I guess.

From: Joseph Stiles
Topic: 30610 Message: 30682

Mike & group,

Q1 voltage values: No plug in CW jack..power ON, heater-OFF. send/rcv in
RCV: B=0v, C=8.9v, E=1.6mv

"""""" """""
"""" send/rcv in SEND: B=.7mv, C= 8.99v, E=1.0mv

CW key plug in CW jack, send/rcv in RCV:
B=1.2mv, C=8.99v, E= 226mv

"" "" ""
"" " SEND/Key down: B=0v, C=9v, E=18mv

From what I understand from the voltage levels is that...Q1 appears to have
failed....on what i THOUGHT was a "known good" AF board. Does this appear to be
correct?, or should I look after this transistor? Please remember...I am not
the sharpest diagnostic pencil in the box...but I'm
trying...hihi...................

Subject: Re: [TS-520_820_530_830] Re: TS-830S CW problem

Mike,

I think I should check the voltage levels as listed for the Q1. Maybe...the
"known good" AF-AVR board Q1 was/is bad also....just my luck...Oh
well..........gives good experience....I guess.

Subject: [TS-520_820_530_830] Re: TS-830S CW problem

Joe,

Q1 is on the AF board and Q1 is the side tone oscillator. If the side tone
oscillator fails for what ever reason, there will be CW side tone resulting in
no CW break-in.

The 830 high resolution schematic I have shows AF Unit Q1 voltages as follows:

Base - 3.5VDC
Collector - 6.6VDC
Emitter - 3.6VDC

Those voltages are with nothing plugged into the CW socket and MODE switch set to TUNE.

If replacing Q1 doesn't fix the problem you might check the diodes, there are 3 diodes. Two diodes are 1S1555 and the other is WZ-090. The WZ-090 diode is a 9 volt zener and the 1S1555's are simple silicon diodes.

I seriously doubt the fix capacitors are the source of the problem. C6 is a 10ufd 16VDC electrolytic but I doubt that is the problem.

30684. Re: [TS-520_820_530_830] Re: Full ALC deflection when tuning

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-04-05 02:04:33 UTC
From: John Davidson
Topic: 30518 Message: 30684

When my TS520 was new I got barely any ALC movement on 10 M when tuning up but got about 75 W out key down.
Good ALC deflection on all the lower bands, at least 100W output.
 Now nearly 40 years later, on the 2nd set of tubes, I only get about 60W on 10M but still 100w on the lower bands.
Lately I just leave the rig on 80M and my 80M dipole connected due to wear and tear on the band switch. It looks like a real pain to remove and replace all the wiring on that bandswitch ! Gave up After several attempts at cleaning the contacts since that only caused temporary correct operation of the band switch.

Subject: [TS-520_820_530_830] Re: Full ALC deflection when tuning

Not getting full ALC deflection on every band, especially the higher bands, is normal.

In fact for the TS-520, I believe that Kenwood has said that no ALC deflection is normal for 10M, although many people report getting substantial ALC transmit indications on that band.

Substantially less output on the higher bands is a common indicator of weak final tubes.

I assume the output you are measuring is CW. The only way to reliably measure SSB output is by feeding the mike input with middle, low and high frequency tones from an audio signal generator to explore the passband of the SSB filter. This is the procedure recommended by INRAD.

Is your ALC deflection steady or does it sag off after the first couple of seconds of transmit? If it does that is an indicator of a weak driver tube.

Finally, of course, you should consider aligning the driver coils.

Regards,

Robert

I have done an intial clean and check of the TS-830S Gold Edition that I found locally.

It was really fairly clean inside. A liberal application of compressed air helped a lot.

Opened up the HV section and did a visual inspection. Everything looked good. It looks like the gentleman took pretty good care not to overdrive the rig, and tuned it up well.

A quick load test showed full 100W output on 20M. I didn't test any other band, though, because I have a bandswitch problem -- it's *very* loose in the detents and if you don't have it *just so* the VFO won't be active. I did run it all the way around and while it does work on all bands it isn't as solid as my -530SP. So, I gather I'll either need a new bandswitch or to repair this one. Is there a way to do this? I haven't looked at it closely yet -- I just finished checking out the rig, and I've been working at stuff all day today and I don't want to go poking around in there just yet. If it's a replacement, I'm okay with that (I guess). If it's repairable, I'm not sure exactly how I should proceed. Suggestions?

Thanks,

Tony KA5TRO

Subject: [TS-520_820_530_830] Nice find!

While perusing our local craigslist this week, I found an ad for some ham gear for sale. Seller listed a Kenwood TS-830S, a VFO-240 and an AT-230, along with some other goodies (and baddies).

Well, I contacted the seller, who had already fielded dozens of calls wanting to low-ball him an offer -- it was his late grandfather's station, and the grandfather had passed away while the man was in the Army. Now that he's out/retired, he's getting rid of all the stuff he inherited, including his Ham station.

So, we talked a bit, and he told me to come and take a look. So I did. I guess he liked me shooting straight with him, as I made him an offer on the gear and he sold it to me.

Turned out the 830S is a Gold Edition and looks to be in nice enough condition. Everything looks to be well-used, but not abused, and most of it should clean up nicely. Grandfather was a CW operator, so the only filter in the 830S was a CW filter, so I'll be adding filters, assuming the rig checks out okay. And I've already got a VFO-240 and AT-230, so these will be redundant.

If the rig checks out well and cleans up as nicely as I expect it to, I'll probably keep it and sell my 530SP, which is in very nice condx, along with the extra VFO and AT.

Grandfather also had a big amp and tuner, and I hope *those* check out as well. Not sure what I'll do with those, yet, as I don't really have the setup to run QRO here, but might hang on to them anyway if I ever do. Might happen in a few years, once the kids are out of school and if I get my druthers and move out into the country somewhat. (I'm not CCR restricted, but I *am* XYL restricted. And I have other hobbies that will do better out away from the city anyway.)

So, for those of you who resurrect these rigs on a regular basis -- any suggestions for what I should or should not do? My thoughts were to blow the majority of the dust and crud out of the rig with compressed air, and then power it up (soft start? I do have a variac) and see what happens. I can do output tests easily enough into a dummy load, check the VFO for operation, check the TX freq with a counter I have. Any other major points I should consider? The gear has been sitting since 2003, so I'm concerned about caps. Am certainly interested in hearing what else I should look for or be concerned about. I bought the lot primarily for this rig (and the big amp and tuner, assuming both work) and the rest is gravy that I think I can sell and make my investment back (without necessarily selling my 530SP). But we'll see.

Thanks for reading.

Tony,

I have replaced about 30 or so broken/cracked bandswitch couplers. The switch in the final cage area is pretty robust. I have not seen one that is truly broken. Replacement of the coupler is rather easy...the hard part is getting a long enough allen wrench to get at the screws. Follow K4EAA's instructions...especially about the HIGH VOLTAGE!

Make sure you observe correct alignment of the shafts...there's plenty of coverage in prior messages about this....good luck....

30689. No ALC and No Output on TS-820

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-04-06 02:45:46 UTC
From: vinnievision
Topic: 30689 Message: 30689

Hello all,

I hope you guys can help with this problem.

I bought a TS-820 that has been lying around idle for some time. Looks pristine and appears not abused with the original outputs. It came with a dirty VFO which I cleaned and the receive is very good. If this is any indication, I have been spraying pots, connectors and switches.

There is no ALC and therefore no output. Yes, the SG switch in the back is "on". No ALC deflection on the meter on tune. I set the mode switch to CW and can "guess" at the settings for 20M and set the drive and plate with the carrier control at 3/4 up to get 10 watts output max. (anybody want a QRP rig?)the IP when I do that is about 90ma. On USB in this mode I can shout in the mike and deflect the meter to 10 watts. I traced the ALC line back to The RF board X44-1150-00 on the RF-3 connector pin 6 (ALC) I measure 2.56 volts. It remains steady no matter where I adjust the drive control, or whether I get 10 watts out or 0. FG pin 9 goes from -110v to -56 volts when I key up on CW, but still no ALC and no output. The bias is good at 60ma. I have also traced the ALC line to the IF board and it is has continuity. I have re-seated the RF board and the relay. Now I'm wondering whether Q5 is gone on the board, but before I go in that direction - wondering what else I'm missing here. Also thinking whether I can connect a battery to pin 6 to drive the ALC below 2 volts and whether that would get some output -- but don't want to blow Q5 if it is still good.

Great looking radio, would love to get it running.

Hello Vinnie,

Don't start replacing components yet and do not apply a battery voltage to the ALC line! You accomplish absolutely nothing by applying a battery voltage to the ALC line and you could end up creating more problems than you already have.

Transmitter ALC does NOT "increase" power output, it "reduces" power output but ONLY when grid current flows in the final tubes! If you have been told that the higher the ALC indication the higher the power output then you have been mislead.

ALC is produced ONLY when grid current flows in the final tubes. The only time grid current will flow in the final tubes is when the RF sine wave signal from the driver is at a level that causes the final tube grids to swing positive.

There are a couple of things you should check first;

1. Check resistors R5 and R6 on the HV Unit board. Both are 56K 1/2 watt.

2. Check and if necessary, perform the COIL PACK DRIVER adjustments. Procedure is contained in the 820 service manual. Service manual is available for download, free, at www.n6wk.com/kenwood/

3. Clean the band switch wafers

4. Check and clean ALL PC board plugs and pins.

5. Check all PC board mounting screws. Most all of them provide a ground return for the PC board. These areas must be clean and making good connection.

6. Measure the Rectifier Unit DC voltages at the following Rectifier Unit terminals

6A - 800 (this is the final amplifier's high voltage. It should be approximately 900VDC or so in standby (receive) and slightly less in transmit with idling current flowing in the final tubes.

6B - 300A, 300B, 210A, 210B

If you do not have the operator and service manual then I recommend you obtain both of them. You can't service the 820 without the service manual.

Mike,

Thanks for this task list. You have come up with a couple of ideas I have not thought of. I have the service manual and will get to work -- it will be a few days until I get back to the shack and will report back. It makes sense that the problem could be a corroded pin connection on one of the boards or mounting screws. This radio has been on the shelf too long

> >
> > There is no ALC and therefore no output. Yes, the SG switch in the back is "on". No ALC deflection on the meter on tune. I set the mode switch to CW and can "guess" at the settings for 20M and set the drive and plate with the carrier control at 3/4 up to get 10 watts output max. (anybody want a QRP rig?)the IP when I do that is about 90ma. On USB in this mode I can shout in the mike and deflect the meter to 10 watts. I traced the ALC line back to The RF board X44-1150-00 on the RF-3 connector pin 6 (ALC) I measure 2.56 volts. It remains steady no matter where I adjust the drive control, or whether I get 10 watts out or 0. FG pin 9 goes from -110v to -56 volts when I key up on CW, but still no ALC and no output. The bias is good at 60ma. I have also traced the ALC line to the IF board and it is has continuity. I have re-seated the RF board and the relay. Now I'm wondering whether Q5 is gone on the board, but before I go in that direction - wondering what else I'm missing here. Also thinking whether I can connect a battery to pin 6 to drive the ALC below 2 volts and whether that would get some output -- but don't want to blow Q5 if it is still good.

Don,

I have a TS520s and had a similiar issue , that when tunning-up I could not get a full meter reading to load & plate .

have you checked RF VOLTAGE ?? , or do you not have to do this on the 830?? I am not familiar with the set , or the tunning process.

I found that the RF VOLTAGE was low and on the 520S , this can be adjusted via an access panel on the left side of the rig.

Once i had readjusted this to the recommended 2/3 of the meter sweep, the set works correctly.

cheers,

Jeff

Don ,

Just another thought as well , on E-HAM in the froum , there is a section called ASK ELMER" this is for questions to be naswered , I have had good replys from this group ,.

all you need to do in registar , and ask your question, ..

Jeff and others,

The RF Volt pot setting has no control over the actual RF output level of the transceiver. The RF Volt pot only controls the level of rectified RF being fed to the meter's "RF" switch setting, nothing more. None of the meter scales are used. The only thing to be viewed is the position of the meter pointer when setting the RF VOLT pot, nothing else.

If one looks at the schematic, there are only a few components, couple of fixed resistors (voltage divider), a diode to rectify the RF into a DC voltage, and the pot to vary the DC voltage level applied to the meter switch RF setting.

I was checking several boards for any cold solder joints, broken traces, etc. and found a couple that needed addressing. I also noticed that on the IF board, there seems to be a couple of traces that were purposely cut out. Can anyone tell me if this is normal? I can send a picture if you should need one. Thanks. 73 Steve

Meter switch to ip mode, only reading 60ma idle current. No RF. I know that when I used to hit send, the meter would "bounce up" a bit and return to nil. Now it doesn't do that anymore. I also notice that the receive is acting funny. The marker signal is very weak and sometimes isn't there at all. I remember once the other day when tuning in the marker signal, that it faded out to barely audible with the volume all the way up. The cw sidetone is plenty loud. It's as if there isn't anything there for the finals to work with signal wise.

Hi Mike
well i did as you said re the coil pack and they did need adjusting
i did try the carrier adjustment but it seemed fine
i did try a mic to see how it would work and hardly got any movement on the meter
however when i pushed the proc switch on the power and the reading came up to normal

thank you

Don and others,

Not all problems have a "quick fix" such as replacing a tube. There are some problems that require a lot of troubleshooting such as taking voltage measurements, physically inspecting the PC boards and connections. Knowing how to read a schematic/wiring diagram is important to being able to trace a signal through the equipment from beginning to end. Also understanding the basics of how each individual stage works and contributes to the successful operation of the next stage is very important. For example, a failed transmit mixer will result in the transmitter failing on ALL bands but the receiver will work fine. A failed filter select diode on the IF board will affect both transmit AND receive. The same goes for the VFO, if the VFO fails then everything fails.

Most operator and service manuals have a section devoted to circuit description. This section also contains the block diagram. A block diagram can tell a lot about the equipment and how individual stages work together to produce the end product. If one intends on servicing their own equipment, reading the circuit description, studying the block diagram, and learning how to read a schematic and wiring diagram are very important. Also learning basic electronics is also important. Many times I have referred to a book that can teach basic electronics, "Basic Radio Course" by "John T. Frye". This book is no longer in print. That doesn't mean the information contained in the book is out dated. Basic electronics is the same now as it was when John's book was first written in the early 50s. A resistor and capacitors do the same thing today as they did in the 50s. A vacuum tube's ability to amplify a signal does it in the same fashion today as it did in yeas gone bay.

If your intent is to repair your own ham gear then take the time to learn basic electronics, read the equipment manual's circuit description section, ask questions about something you don't understand, and never assume anything! A ham license does not always convey electronic knowledge. I'm no expert, never cared for the word "Expert". There is always something new to learn either through research, by experimenting, or from another person.

Don,
I suggest you clean the Proc switch with De-oxit.
These small switches for the Proc, fixed, etc etc etc are too often
overlooked when cleaning.
They cause many issues just like a lack of ALC or movement on the meter.

Great posting and it's is very true in what you said,but some times i get lazy and looking for a time saver,not fair i guess
I had a set of bad tubes and not matched so would need them anyway
My eye's are not what they use to be so that does not help either
I will make a print out of this post

thank you so much mike

There are some problems that require a lot of troubleshooting such as taking voltage measurements, physically inspecting the PC boards and connections. Knowing how to read a schematic/wiring diagram is important to being able to trace a signal through the equipment from beginning to end. Also understanding the basics of how each individual stage works and contributes to the successful operation of the next stage is very important. For example, a failed transmit mixer will result in the transmitter failing on ALL bands but the receiver will work fine. A failed filter select diode on the IF board will affect both transmit AND receive. The same goes for the VFO, if the VFO fails then everything fails.
>
> Most operator and service manuals have a section devoted to circuit description. This section also contains the block diagram. A block diagram can tell a lot about the equipment and how individual stages work together to produce the end product. If one intends on servicing their own equipment, reading the circuit description, studying the block diagram, and learning how to read a schematic and wiring diagram are very important. Also learning basic electronics is also important. Many times I have referred to a book that can teach basic electronics, "Basic Radio Course" by "John T. Frye". This book is no longer in print. That doesn't mean the information contained in the book is out dated. Basic electronics is the same now as it was when John's book was first written in the early 50s. A resistor and capacitors do the same thing today as they did in the 50s. A vacuum tube's ability to amplify a signal does it in the same fashion today as it did in yeas gone bay.
>
> If your intent is to repair your own ham gear then take the time to learn basic electronics, read the equipment manual's circuit description section, ask questions about something you don't understand, and never assume anything! A ham license does not always convey electronic knowledge. I'm no expert, never cared for the word "Expert". There is always something new to learn either through research, by experimenting, or from another person.

In case anyone needs one here is an auction item number to check out:

330550802229

No vested interest. Buy it now price is $75 plus shipping. No bid yet and starting bid is $50. Might help someone out and I can't comment on the price versus value.

Cheers,
Larry, KS7J

Note: Joe was nice enough to reply to an email about the alignment procedure and give some other tips. For some reason this post didnt seem to get any response so i putting the question out for the group again. I had a hard time finding it myself.

steve

Hi all

After a successful tube change and neutralization, I decided to align the receive per the manual. I went through all the bands and tweeked the Antenna and mixer coils for max meter reading using the cal signal. I could not get the meter to move much if any except for the 20 meter band, that I could bring up a bit, the other bands didnt seem to respond. I did them in order, on the proper freq with the tuning tool. I hope i put the coils back to where they should be. The cal signal was lowest on 28 mhz .

Thanks

Steve

any suggestions?

Don, I can understand having those moments where a quick fix would be nice. We all have those once in a while.

You mentioned you had a set of bad tubes and that the tubes were not "matched". I can only assume you mean the final tubes, 6146Bs.

Kenwood as well as many other manufacturers didn't install matched 6146 tubes when the transceiver was manufactured. The final amplifier operates in "parallel". There is no benefit using matched tubes. Therefore, I recommend you not waste your money on matched tubes. However, if that's what you want then that's entirely up to you.

Hi Mike
that's very interesting and first time i have heard that
Not saying you are wrong but will keep that in mind the next time i buy some
I was lucky to get a set of matched tubes plus the driver at a ham fest for$50,so i grabbed them as they were new or old stock
I am lucky to have two more 830s in mint shape with about 15 hrs total
on one and 25 hrs on the other
Why i kept this one was the fact it had the dc power supply
Getting to be my busy time of the year so i might have to send it out for a check up
thanks again Mike
73s
Don

>
> You mentioned you had a set of bad tubes and that the tubes were not "matched". I can only assume you mean the final tubes, 6146Bs.
>
> Kenwood as well as many other manufacturers didn't install matched 6146 tubes when the transceiver was manufactured. The final amplifier operates in "parallel". There is no benefit using matched tubes. Therefore, I recommend you not waste your money on matched tubes. However, if that's what you want then that's entirely up to you.

> > >
> > > Don and others,
> > >
> > > Not all problems have a "quick fix" such as replacing a tube. There are some problems that require a lot of troubleshooting such as taking voltage measurements, physically inspecting the PC boards and connections. Knowing how to read a schematic/wiring diagram is important to being able to trace a signal through the equipment from beginning to end. Also understanding the basics of how each individual stage works and contributes to the successful operation of the next stage is very important. For example, a failed transmit mixer will result in the transmitter failing on ALL bands but the receiver will work fine. A failed filter select diode on the IF board will affect both transmit AND receive. The same goes for the VFO, if the VFO fails then everything fails.
> > >
> > > Most operator and service manuals have a section devoted to circuit description. This section also contains the block diagram. A block diagram can tell a lot about the equipment and how individual stages work together to produce the end product. If one intends on servicing their own equipment, reading the circuit description, studying the block diagram, and learning how to read a schematic and wiring diagram are very important. Also learning basic electronics is also important. Many times I have referred to a book that can teach basic electronics, "Basic Radio Course" by "John T. Frye". This book is no longer in print. That doesn't mean the information contained in the book is out dated. Basic electronics is the same now as it was when John's book was first written in the early 50s. A resistor and capacitors do the same thing today as they did in the 50s. A vacuum tube's ability to amplify a signal does it in the same fashion today as it did in yeas gone bay.
> > >
> > > If your intent is to repair your own ham gear then take the time to learn basic electronics, read the equipment manual's circuit description section, ask questions about something you don't understand, and never assume anything! A ham license does not always convey electronic knowledge. I'm no expert, never cared for the word "Expert". There is always something new to learn either through research, by experimenting, or from another person.

One question Don. Why did you decide to buy matched final tubes in the first place?

Hi Richard,

There were two similar (goofy) looking microphones made by Kenwood.
One is the MC10 which is a 50Kohm impedance and the other is the MC30
which is low impedance 600 ohm mic. The MC10 is the right one for
you. How can you tell which mic you have? Look on the back of the
mic. The MC10 will have a sticker saying 50kohm and the MC30 will
have a little moulding stamped with 600 ohms.

because the guy had them for sale and stated they were matched and i have heard that they should be matched from another seller,but the manual does not say that they have too be matched
This tube guy i know has said this and when i talk to him the next time i will ask him were he gets that info from or to define it
He has been selling tubes for humppy years but that does not mean he is right
I guess as long as they are tested good they will work
I would think a 6146a and 6146b would still work and they do not have to be from the same company

Don,

I can't see why anyone would NOT want 2 x 6146B's or 2 x 6146's or 2 x 6146W's (assuming that this is what you mean by "matched" Don.
makes a lot of sense to me.....

Cheers
Chris

"Matched" tubes does not mean that they are two of the same kind but rather that they are electrically matched to have similar characteristics and outputs. In other words, they sampled a bunch of tubes of the same type and chose two that are similar in characteristics. This is more commonbly done for audio circuits, where distorsion is to be avoided.

It is indeed true that you should use two tubes of the same sub-type, as in S-2001A, 6146, 6146A, 6146B, 6146W, 8298, 6883, 6293, etc.

The final amplifier's in the hybrids, along with many other transceivers with tube amplifiers such as Heathkit, Collins, Yaesu, and Swan to name a few, are not "Push-Pull".

In other words, they sampled a bunch of tubes of the same type and chose two that are similar in characteristics. This is more commonbly done for audio circuits, where distorsion is to be avoided.

No, "matched pairs" means you apply a certain amount of Plate and Screen voltage, and Grid Bias, and each tube's current draw will be very close to the same with the control voltages being identical for each tube.

The reason matched tubes are quite important in Push-Pull circuits is that one tube amplifies the positive swing of the input voltage, and the other one handles the negative swing.

Actually, both tubes are working with a certain amount of negative voltage being appied to the grid of the respective tube, and positive voltages to the plate and screen, but the inputs and thus the outputs are handled in such a way that the entire waveform of the input signal is amplified. But just the part that appears at the input to the circuit going negative is handled by one of the tubes, and the part that appears at the input to the circuit as going positive is handled by the other tube.

It's done by transformers in audio work, and usually by phase splitters or specialized RF transformers in RF applications.

Sorry guys... was in meetings this afternoon...

Just to clarify one thing...

I didn't assume that "matched tubes" means matched sub-type tubes (as in 6146, 6146B etc)... I was saying that IF that is what Don meant, then there would be no reason not to buy a matched sub set... I should have been clearer in my reply.

Cheers
Chris

On the subject of matched pair
could also mean both tubes from the same company
Guess it would be ok if you were stuck and mixed them,but i have always tried to keep them from the same maker
Also what would happen if you put one 6146a and one 6146b or w together? as a pr if that's all you had on hand

ah summer time is coming,cottage time and antenna time,beer time
73s all

30730. Correct value of C-75 in TS-820 IF Board

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-04-08 16:35:20 UTC
From: ae5uu
Topic: 30730 Message: 30730

Good morning,

I am recapping the IF Board in my TS-820. In the parts list, C-75 is listed as a 0.01uf +80% -20% ceramic, Kenwood part # CK45F1H103Z

What I just took out of there, as I cleared off all the electrolytics, is a 1uf 50wv electrolyic.

To add confusion, the board is clearly marked with polarity for C-75, which lends strength to the electrolytic being correct, not withstanding what the parts list says.

Does anyone have any thoughts on this?

73,

Russell
AE5UU

Topic: 30730 Message: 30731

Russell,
My Schematic for the IF board of the 820 shows C75 as 1pf @ 50wv
electrolytic that is .001uf @ 50wvdc
If you look in the parts section listing, they show (2) C75's
one is an 1PF Electrolytic part number CE04W1H010(RL)
The other C75 is a ceramic disc that is .01uf +80% -20%

I seriously doubt that they even manufacture an electrolytic with that low a capacitance !
One MICROfarad, now I could almost believe that !

30734. Re: [TS-520_820_530_830] Correct value of C-75 in TS-820 IF Board

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-04-08 18:02:07 UTC
From: Dennis Windle
Topic: 30730 Message: 30734

Looking at an IF board both C73 & C75 are physically 1UF 50WV Electrolytic's. I believe in the parts list the 1PF listed for C75 is a typo for 1uf as 1pf would actually be .000001uf (1X10 -12) or .001 Nano Farad (1X10-9) if I remember right. The part # listed for both C73 & C75 are the same except for the (RL) at the end of the part # and I am not sure what that means ??

You are correct Dennis.
1pf is .000001Uf my error
I agree, the Service manual is in error, but there are many errors in
the 820 Service manual that I and Ken, K4eaa, have discovered.

Best 73,
Gordon

Forgot to mention that the second C75 listed in the parts list should
actually say C76 which is a .01 Disc by the base of Q17 so it is also
another typo.

I've never seen a service manual that was 100% accurate, or didn't leave you with at least a couple of "HUH ? ? ? " moments !

Especially those that come from the far East.

[Non-text portions of this message have been removed]

30739. Thank you all for your advice on the correct value of C-75 in my TS-820 IF Board

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-04-08 18:53:38 UTC
From: ae5uu
Topic: 30739 Message: 30739

On my schematic there are two C-75s, clustered around Q-16, as you have pointed out. In my parts list, the entry is: "C-75, C76 (as one line item) @ .01uf ceramic =+80%-20%

So in summary, C-73 and C-75 are in reality both 1 uf 50wv, while C-76 (also labeled C-75) on the schematic is .01 uf ceramic.

Thanks everyone.

73,

Russell
AE5UU

I would like to get down your way some time mate
I use to talk to lots of vk's when i had my 10 meter telrex monobander up many years a go

lots of ham's in your country with 30 to 40 thousand head of sheep.Don't know were they got the time to chat and to watch sheep and drink beer lol

did not get much of a response to my questions on here ,so i just reworded it and really got some nice feedback

thank all

All the best
Don

30741. Audio Problems with 520S

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-04-08 23:01:39 UTC
From: keith.colgan
Topic: 30741 Message: 30741

I've had my TS-520S since about 1974. About 2 years ago I had it gone over completely by K4EAA in Fla (I believe). After its return (to CA) it worked fine on 20 mtrs, but a few months later I tried it on 40 mtrs and the audio was slow to come on. The S-mtr would indicate strong signals, but the audio would lag several seconds and then ramp up quickly to normal levels. This got progressively worse until finally the audio never came up and the symptoms spread to 15 and 20 mtrs. K4EAA suggested that maybe I needed to adjust the coils that are accessible from the bottom of the rig. I purchased plastic adjustment tools, but have been reluctant to make any changes due to lack of real electronics experience. I've replaced the rig with a FT-950, but I'm getting interested again in resolving the 520S issue. I love the rig and hate to see it idle for want of a few turns of the screw. Has anyone seen this problem and can anyone inspire me to dig in and try to fix it.

Thanks,
Keith - N7DXC - Lodi, CA

30742. TS-520S LSB crystal slow to start

Topic: 30729 Message: 30742

Hi Everyone,

I have a TS-520S with a lazy LSB crystal that takes a few minutes to start oscillating on power up. Voltages on the carrier board are OK and I've tried adjusting TC3 and T1 over a range to see if there's a sweet spot where the crystal will start every time but no success. What next?

Lou,
I posted, a few minutes before yours, an issue whereby the audio on some bands would ramp up after a minute or so with my 520S. I thought it may have been due to cool temps in the shack, but it does it now all the time. I will follow the replies to your posting with interest.

Anyone have a source for a replacement leather carry handle for an early TS-520.

The only close replacement that I've found is the later vinyl version.

Thanks

Check with Bob Mansker, KE5FTF. He has Kenwood straps and nice ones at that. As I recall around $22.00-$25.00. Don't quote me. I bought one for an 820S and it was like new.73s,Butch LewisKØPSA

Lou & all,
I had the same problem with only the LSB osc working intermittantly but before I could order a new XTAL it came back to normal operation. I rarely use the TS520 on SSB (Been well over a year since I did anything besides CW with this rig) But it's nice to know it works when I do a monthly test..

I found some help from another Kenwood Hybrid enthusiast and a fellow in GB when I had this same inquiry when I bought my TS-830S last summer.

It seems like the first digit in the SN minus 2 gives the year and the next 2 the month and the last 4 the number of the radio that was made that month.
However that puts my radio a year earlier than most of the dates I found in the radio. Kenwood placed the manufacture of my radio a good 5 years before any component date code in the radio. So either mine has futuristic ICs in it, was totally rebuilt, or the Kenwood information is totally wrong.

If you open the rig you should be able to locate IC date codes. The LSI chip in my radio was made the latter part of the year before any of the other date codes in my radio. So to make a long story (mine is way too long) short. Kenwood did not use a serial number date/manufacturing run method like Yaesu did. You can probably get close to the actual year or the year before using the serial number method.

Check G4FUI's site where he has some dating examples:
http://www.g4fui.net/rigs_frameset.html

Note: Joe was nice enough to reply to an email about the alignment procedure and give some other tips. For some reason this post didnt seem to get any response so i putting the question out for the group again. I had a hard time finding it myself.

steve

Hi all

After a successful tube change and neutralization, I decided to align the receive per the manual. I went through all the bands and tweeked the Antenna and mixer coils for max meter reading using the cal signal. I could not get the meter to move much if at all, except for the 20 meter band, that I could bring up a bit, the other bands didnt seem to respond. I did them in order, on the proper freq with the tuning tool. I hope i put the coils back to where they should be. Cores felt good, not stuck, cracked etc.
The cal signal was lowest on 28 mhz .

Thanks

Steve

30755. TS-830S ALC meter issue?

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-04-10 01:17:05 UTC
From: joe
Topic: 30755 Message: 30755

Hello to all on the group!

I just joined the a few weeks ago and this is my first post.

I recently became the owner of a very nice TS-830S. I really like the transceiver very much! It is in very clean cosmetic condition and works exceptionally well. I have noticed one issue that I was hoping someone might be able to assist me with.

There seems to be an intermittent problem with my meter in the ALC position. Sometimes the meter will not read any deflection in ALC mode. Other times it works fine. Even when this happens, I can still tune the transmitter to 100+ watts output on all bands (with plate current at about 225 mA.) I do this by using my external watt meter to peak the ALC in tune. My meter functions just fine in displaying the plate current, RF, compression, and HV.

Again, this problem seems to be intermittent. Sometimes the meter will read ALC as it should, other times it will not. The issue does not seem to be band specific. In other words, when the ALC isn't reading...it isn't reading on any band. Conversely, when it is working... it's working on all bands.

Here's what I've done thus far to troubleshoot it... Replaced 12BY7A driver, no change at all. Sprayed DeOxit cleaner on the meter switch and exercised the switch liberally. Initially, I thought this may have helped, but after a day or two the problem has come back.

Does anyone have any suggestions or ideas on how to fix this? I was hoping someone else may have had an issue similar to mine.

Many thanks!

After a chat at my local ham radio club I thought about the way we go about repairs to our equipment. One of the things that can go wrong with any radio is poor or intermittent switch contacts. There are a range of cleaning products that you can use to clean switches. How often do you hear "I used a whole can on that switch". My reply is normally "Really, a whole can?" Consider that everything that drips off the switch is wasted as it gets nowhere near the contact and doesn't help one little bit to clean the contact. You don't need more that a drop applied to the contact for it to do it's work. Better to use a small amount on the contacts and exercise the switch. Using your cleaning product carefully results in less mess and helps you pocket too.

Joe,

I had the same problem with mt TS-530SP: unstable ALC reading on the S-meter and sometimes S-meter reading itself.
You need to examine relay RL-1. I replaced the relay with I ordered from K4EAA. See here his story about RL-1: http://www.k4eaa.com/RL-1.htm

Good luck and best 73's Ger, PE1CZG

Hi Keith,

From the symptoms you describe I think we have two different problems. You say the problem occurs on 40,20 &15 and even though you have S meter indication you have no audio. If the carrier osc doesn't work you won't get any S meter deflection and since you have the problem on bands that use two different crystals for the carrier osc it's even more unlikely that the problem lies in that area. Again, because you have S meter deflection I think the receiver is working fine and perhaps the place to start looking is around the AF stage.

Hi John,

Well that would be nice if it came back but I
think swapping the crystal out might be the best
solution. I recall something about giving a lazy
crystal a hit of RF to get it going again but I'm
not sure how to go about that. For the moment, I
leave the radio on standby and it gets me out of trouble.

30761. Re: TS-830S ALC meter issue?

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-04-10 14:00:04 UTC
From: w5rkl
Topic: 30755 Message: 30761

Ger,

You said you can tune the 830 up and get 100 watts output using an external watt meter. What mode are you using to achieve 100 watts output? The 830 will not produce 100 watts output in TUNE mode. In CW mode, however, you can achieve 100 watts output.

If you are tuning the 830 up in CW mode and while watching you external watt meter, do you see any intermittent or instability in the RF output? If not then it's quite possible the source of your problem is not the AF unit relay.

Since you are not the original owner it's quite possible a previous owner may have experienced a similar problem and was instructed to replace R15 and R16 on the Rectifier Unit. If the previous owner's soldering skills were poor, there may be an intermittent poor solder connection to one or both resistors which is contributing to your intermittent problem. Therefore, I would check the solder connection to R15 and/or R16 before moving on to relay RL1 on the AF Unit board.

I also would not discount a fractured foil run on a PC board either. The foil runs are very thin and easily broken if excessive heat is applied when soldering a component lead. This is common in these hybrids.

If your Kenwood has not been modified or had modules swapped in a repair, the most reliable way to date your radio is to read the date codes on the ICs or other date coded components. Usually the ICs are the easiest to decode since most semiconductor manufacturers date or lot code their parts for tracing in case there is a defect or test issue in the manufacturing process. Also, most systems manufacturers, such as Kenwood, use only relatively "fresh" IC components, not parts that have been on the shelf for several years. This is why ICs are the best to use.

In case you are not aware of the codeing process, one of the most common is a 4 digit code that has as the first two digits the year of manufacture and the next two digits are the week of the manufacturing. For example 8327 would be 1983, first week of July. Check several different types of parts and see if most are within a few weeks range. It is a good bet that the date of your Kenwood is about 3 months younger than the latest date codes you can find on the ICs. I am not certain if Kenwood stamped test or acceptance date codes on assemblies, but if they did that is a better approach or at least a great cross check.

Hope this helps.

Topic: 30755 Message: 30764

Okay Ger and Mike...thanks for the replies and suggestions.

Mike,
I did forget to mention that I use TUNE mode to pre-tune the 830 then switch to CWW to tune to the rig to 100 watts. I see absolutely no fluctuation in RF output at all. Its rock solid.

I'll inspect R15 / R16 and also have a look at the foil runs from the PC boards. I'm guessing those aren't any particular easy fix if that turns out to be the problem.

Ger,
My meter isn't intermittent in any other position except ALC. The S-meter functions 100%. I'm not sure if this is the same issue that you had or not but, I'll look into it after checking those resistors out.

73 with regards,

Joe

Topic: 30729 Message: 30765

I managed to track down the original owner for
this radio and it seems the lazy crystal was one
of a number of reasons for getting rid of this
radio. The last person to look at it checked the
crystal in another radio and it was slow there
too. Conversely a know good crystal was tried in
my radio and worked fine. The original owner
didn't want to pursue the repair and surrendered
the set. I'm on the track of a replacement
crystal and that should get the radio back to full operation.

Topic: 30747 Message: 30766

Thank you for the great posting Larry

Can you tell me what this serial number is 1111111 yes seven one's
I have sent him a few photo's of the radio for his site
I can't see any dates on the ic's but maybe i am not reading it right

I have been in touch with Martin [Check G4FUI's site where he has some dating examples:
> > > http://www.g4fui.net/rigs_frameset.html]
This is what he had to say
Hi Don,

As I understand it, the DC-DC convertor (or invertor as it may have been
called) was an "optional accessory" for the TS-830.

I don't suppose there were all that many sold, hence the rarity.

The '830S was really a bit big for mobile operation compared with the
contemporary TS-130S.

The reason for the multipole Jones plug on the radio was to allow the
co-existence of mains 120/240V AC connections (as appropriate for the region
of the world) and 12V DC - in this respect it is the same philosophy of the
older Yaesu FT-101 series. Back in those days there were fewer commercial
"mobile" alternatives.

So it's all quite interesting and you have got yourself an "oddball" bit of
interesting history there!

I don't think the serial number you quote doesn't sound quite right, so I
would be sceptical about that.

You can date your radio fairly well from the date codes on some of the chips
inside if you are up to taking the covers off and having a peek.

The cheaper TS-530S didn't have the multipole power connector, or some of
the mounting holes for the DC unit.

If you could send me some nice photos of your unusual radio, I'd be happy to
feature them on my web site, with your permission of course, if you wish.

Hope this is of some interest

73,

Martin

Hello Rick,

What do you mean when you say, "My alc is set for 45 watts"?

How are you determining that a specific level of ALC is controlling the output to no more than 45 watts? Please explain how you are doing this.

when i tune in cw with 45 in to amp it shows 550watts . and when i go into ssb with it the amp only does 550watts but when i take the alc out of line it does 800watts so that tells me that the alc is only doing 45watts into amp .
thanks Rick

Topic: 30747 Message: 30770

Sorry, Don. I can't date based on the serial number. I am sure if you look hard enough at the tops of the ICs you will find some with 4 digit date codes. There are usually a couple of rows of numbers, the top is usually the part number and then under that will be either a lot code or date code and then under that will be the date code or lot code. Sometimes there is no indication of the lot code, just the 4 digit date code. There is no hard and fast rule about the placement of the date or lot codes but usually they will be under the part number type. Look for codes that start with 8. I am guessing that the radio was produced in the 80s era, I don't remember the range of years. Just a guess on my part. Incidentally, if you see a 3 digit date code then the assumption is that the omitted digit is the year (probably 8) and then the first number is the year then two digits for week. In my prior example, the code would be 327 where 8 is implied and the year would then be 83.

I haven't had the top off my 830 in a while so I can't point you in the right direction under the hood, but with all those chips in there, there must be a few with codes that will help. Keep looking!!!

You might look at the dates on caps, relays, etc., if you can't find an IC or two with readable codes.

Cheers and 73

For example 8327 would be 1983, first week of July. Check several different types of parts and see if most are within a few weeks range. It is a good bet that the date of your Kenwood is about 3 months younger than the latest date codes you can find on the ICs. I am not certain if Kenwood stamped test or acceptance date codes on assemblies, but if they did that is a better approach or at least a great cross check.

my radio was made the latter part of the year before any of the other date codes in my radio.Â So to make a long story (mine is way too long) short.Â Kenwood did not use a serial number date/manufacturing run method like Yaesu did.Â You can probably get close to the actual year or the year before using the serial number method.

Thanks Larry for your post

I will do as you say and check it top and bottom since i have the covers off
It's looking like it might be a 1980

cheers
Don

>
> Sorry, Don. I can't date based on the serial number. I am sure if you look hard enough at the tops of the ICs you will find some with 4 digit date codes. There are usually a couple of rows of numbers, the top is usually the part number and then under that will be either a lot code or date code and then under that will be the date code or lot code. Sometimes there is no indication of the lot code, just the 4 digit date code. There is no hard and fast rule about the placement of the date or lot codes but usually they will be under the part number type. Look for codes that start with 8. I am guessing that the radio was produced in the 80s era, I don't remember the range of years. Just a guess on my part. Incidentally, if you see a 3 digit date code then the assumption is that the omitted digit is the year (probably 8) and then the first number is the year then two digits for week. In my prior example, the code would be 327 where 8 is implied and the year would then be 83.

30772. Re: how to adjust alc

Hello Rick,

Unfortunately ALC doesn't do 45 watts as you say. ALC itself does not produce any power output.

You cannot "preset" a maximum 45 watts RF output in CW mode by adjusting the CAR control then expect to see that same maximum 45 watts output when you switch to sideband mode. That's not how it works.

The CAR control is only used in CW and TUNE mode. When operating in sideband the CAR control is "disabled" and all power output is controlled by the MIC gain along with any ALC produced in the 820's final amplifier.

ALC is a gain control voltage that is produced and applied to earlier stages when the drive to the final amplifier causes grid current to flow. When grid current flows in the final amplifier, power is consumed in the final tube grids. That power consumed in the grids is taken away from the final amplifier's RF output. Grid current also results in distortion in the final amplifier's output signal.

You say by connecting the 820's external ALC connection on the rear panel to the amplifier's ALC connection the amplifier's power output is 550 watts. If you remove the ALC connection between the 820 and the amplifier, power output soars to 800 watts. That's not a 45 watt difference but rather a "250 watt" difference. That 250 watt difference tells me the 820 is driving the amplifier with a lot more than 45 watts. That also tells me that it is quite possible the amplifier's output signal could easily be distorted because the level of ALC voltage being produced in the amplifier is significantly higher than it should be because of the much higher RF driving power the 820 is applying to the amplifier in sideband mode.

You didn't say what you have the 820's MIC gain set at. To achieve a difference of 250 watts based on the ALC connection between the amplifier and the 820, the MIC gain would have to be much higher than 2.

With the amplifier left in standby or turned OFF and the ALC connection between the 820 and the amplifier in place, tune the 820 up for maximum output in CW mode (100 watts). Switch to sideband and set the 820's meter switch to ALC. While talking 2 inches from the microphone in a normal tone of voice, adjust the MIC gain so the ALC meter just starts to flicker above zero then stop adjusting the MIC gain. Don't adjust the MIC gain any higher. This is the point of maximum peak RF output with very little, if any, distortion in the 820's output. Turn the amplifier on and your transmit signal with the amplifier, will be clean.

All too often hams today tend to adjust the MIC gain so they sound "LOUD" at the receiving end. When this happens, the RF output contains distortion which results in splatter causing adjacent frequency interference. Remember, it's not how LOUD you sound but how clean your transmit signal is.

Don't be fooled or convinced by others that you have to have a high ALC meter indication in sideband in order for your transmitter to be working properly. That's wrong. A higher ALC indication does not mean your transmitter is producing more power output.

Hello Peter,

MFJ sells a very nice 407D CW keyer that works very well with the hybrids as well as many other transmitters/transceivers. You need a 1/4" stereo plug connected to your paddle then plug the 1/4" stereo plug into the rear of the 407D keyer. You also need a shielded cable to connect the 407D keyer to the transmitter/transceiver. I use cheap stereo inter-connecting cables. The 830 has a 1/4" CW key socket on the rear panel. You will need a 1/4" mono plug or a 1/4" stereo plug, connected to the 2 conductor cable between the 830 and the keyer. The 407D keyer output is a 2 conductor RCA female socket.

The 407D keyer will operate from an external 12VDC power source or a 9 volt battery.

Mike, you are being too much of a gentleman regarding this issue.

I am afraid that the confusion has entered the amateur radio ranks because another service has totally mis-construed how ALC controls power output, and how amplifiers are driven by transceivers being used as the exciter.

"All knobs full right" has become a mantra among many radio operators, and it is possible that this thread is an indication of what is being taught (or should I say mis-taught) to so many operators these days.

It cannot be emphasized enough that the proper operation of ALC is just a slight deflection of the indicator, be it a true mechanical meter, an electronic equivalent, or even a flashing light, as was used in the older TenTec radios.

Another thing which is not understood by a great number of operators, is the relationship between "peak" and "average" power as created by the human voice.

In CW mode, the peak and average power readings are going to be the same, or very close to the same, because a "key-down" carrier produces 100% of the power that the system can produce, for the whole time the carrier is on.

In SSB mode, because of the characteristics of the human voice, the peak power is going to be the same as the CW power, but the AVERAGE power reading, which most meters will show, is only 25-30 percent of that peak power.

Many operators try to get that average power reading higher, thinking that there is something "wrong" with their radio if they don't see higher numbers. This leads to many bad signals over the air.

The more one can do to educate these operators, the better the bands will sound. Unfortunately, at this point, it seems to be a loosing battle!

Jim AG3Y

Hello Rick,

Unfortunately ALC doesn't do 45 watts as you say. ALC itself does not produce any power output.

You cannot "preset" a maximum 45 watts RF output in CW mode by adjusting the CAR control then expect to see that same maximum 45 watts output when you switch to sideband mode. That's not how it works.

The CAR control is only used in CW and TUNE mode. When operating in sideband the CAR control is "disabled" and all power output is controlled by the MIC gain along with any ALC produced in the 820's final amplifier.

ALC is a gain control voltage that is produced and applied to earlier stages when the drive to the final amplifier causes grid current to flow. When grid current flows in the final amplifier, power is consumed in the final tube grids. That power consumed in the grids is taken away from the final amplifier's RF output. Grid current also results in distortion in the final amplifier's output signal.

You say by connecting the 820's external ALC connection on the rear panel to the amplifier's ALC connection the amplifier's power output is 550 watts. If you remove the ALC connection between the 820 and the amplifier, power output soars to 800 watts. That's not a 45 watt difference but rather a "250 watt" difference. That 250 watt difference tells me the 820 is driving the amplifier with a lot more than 45 watts. That also tells me that it is quite possible the amplifier's output signal could easily be distorted because the level of ALC voltage being produced in the amplifier is significantly higher than it should be because of the much higher RF driving power the 820 is applying to the amplifier in sideband mode.

You didn't say what you have the 820's MIC gain set at. To achieve a difference of 250 watts based on the ALC connection between the amplifier and the 820, the MIC gain would have to be much higher than 2.

With the amplifier left in standby or turned OFF and the ALC connection between the 820 and the amplifier in place, tune the 820 up for maximum output in CW mode (100 watts). Switch to sideband and set the 820's meter switch to ALC. While talking 2 inches from the microphone in a normal tone of voice, adjust the MIC gain so the ALC meter just starts to flicker above zero then stop adjusting the MIC gain. Don't adjust the MIC gain any higher. This is the point of maximum peak RF output with very little, if any, distortion in the 820's output. Turn the amplifier on and your transmit signal with the amplifier, will be clean.

All too often hams today tend to adjust the MIC gain so they sound "LOUD" at the receiving end. When this happens, the RF output contains distortion which results in splatter causing adjacent frequency interference. Remember, it's not how LOUD you sound but how clean your transmit signal is.

Don't be fooled or convinced by others that you have to have a high ALC meter indication in sideband in order for your transmitter to be working properly. That's wrong. A higher ALC indication does not mean your transmitter is producing more power output.

Have you noticed how signals sound on the bands nowdays? Too much audio, too much back ground noise. It seems as though you are suppose to run the audio wide open, the speech processer on way too high and the rit turned just a little bit. The manual explains all this, but I guess they get lost when the rig is unpacked.

You need a 1/4" stereo plug connected to your paddle then plug the 1/4" stereo plug into the rear of the 407D keyer. You also need a shielded cable to connect the 407D keyer to the transmitter/transceiver. I use cheap stereo inter-connecting cables. The 830 has a 1/4" CW key socket on the rear panel. You will need a 1/4" mono plug or a 1/4" stereo plug, connected to the 2 conductor cable between the 830 and the keyer. The 407D keyer output is a 2 conductor RCA female socket.

Subject: [TS-520_820_530_830] Keyer for my TS-830S

I am looking for a code keyer kit to build for my TS-830S so that I can start to us CW again. I have a Bencher iambic key that I need to get some use of HI HI.

73,
Peter

Don, in the Database section of the group there is a folder giving dates for serial numbers which were submitted by original owners of these rigs. The TS-830 data that is there (it's sparse) is below and from this table you can see that the 1111111 number on your radio most likely is from 1980 or 1981. Keep in mind that the distribution chain from parts production to finished goods to distribution to retail outlet to customer could be well over a year, so the radio you have may have been built in 1980 and sold in 1981 or even 1982. Just bounding it to 1980-1981 may be about the best you'll really do.

1050150 TS-830S Oct 4,1981
2050969 TS-830S Feb 24 1982
3110217 TS-830S 05-12-1983

Cheers and 73
Larry, KS7J

> >
> > Sorry, Don. I can't date based on the serial number. I am sure if you look hard enough at the tops of the ICs you will find some with 4 digit date codes. There are usually a couple of rows of numbers, the top is usually the part number and then under that will be either a lot code or date code and then under that will be the date code or lot code. Sometimes there is no indication of the lot code, just the 4 digit date code. There is no hard and fast rule about the placement of the date or lot codes but usually they will be under the part number type. Look for codes that start with 8. I am guessing that the radio was produced in the 80s era, I don't remember the range of years. Just a guess on my part. Incidentally, if you see a 3 digit date code then the assumption is that the omitted digit is the year (probably 8) and then the first number is the year then two digits for week. In my prior example, the code would be 327 where 8 is implied and the year would then be 83.
